This draft report is prepared by the Canadian Agency for Drugs and Technologies in Health (CADTH). The draft report contains a comprehensive review of the existing public literature, studies, materials, and other information and documentation (collectively the “source documentation”) available to CADTH at the time of report preparation.

The information in this report, when finalized, is intended to help Canadian health care decision-makers, health care professionals, health systems leaders, and policy-makers make well-informed decisions and thereby improve the quality of health care services. The information in this draft report should not be used as a substitute for the application of clinical judgment in respect of the care of a particular patient or other professional judgment in any decision-making process, nor is it intended to replace professional medical advice. While CADTH has taken care in the preparation of this draft document to ensure that its contents are accurate, complete, and up to date as of the date of publication, CADTH does not make any guarantee to that effect. CADTH is not responsible for the quality, currency, propriety, accuracy, or reasonableness of any statements, information, or conclusions contained in the source documentation. CADTH is not responsible for any errors or omissions or injury, loss, or damage arising from or relating to the use (or misuse) of any information, statements, or conclusions contained in or implied by the information in this document or in any of the source documentation.

This draft document and the information provided are prepared and intended for use in the context of the Canadian health care system. Other health care systems are different; the issues and information related to the subject matter of this document may be different in other jurisdictions and, if used outside of Canada, it is at the user's risk. This disclaimer and any questions or matters of any nature arising from or relating to the content or use (or misuse) of this draft document will be governed by and interpreted in accordance with the laws of the Province of Ontario and the laws of Canada applicable therein, and all proceedings shall be subject to the exclusive jurisdiction of the courts of the Province of Ontario, Canada.

CADTH takes sole responsibility for the final form and content of this document, subject to the limitations noted above. The statements and conclusions in this draft document are those of CADTH and not of its advisory committees and reviewers. The statements, conclusions, and views expressed herein do not necessarily represent the views of Health Canada or any Canadian provincial or territorial government. Production of this draft document is made possible by financial contributions from Health Canada and the governments of Alberta, British Columbia, Manitoba, New Brunswick, Newfoundland and Labrador, Northwest Territories, Nova Scotia, Nunavut, Prince Edward Island, Saskatchewan, and Yukon.

This draft report is shared for feedback and comments and should not be used for any purposes other than for consultation. The report may change following this consultation.

Please contact CADTH's Vice-President of Corporate Services at [corporateservices@cadth.ca](mailto:corporateservices@cadth.ca) with any inquiries about this notice or other legal matters relating to CADTH's services.

## ABBREVIATIONS

ASA	American Association of Anesthesiology
CI	confidence interval
CPR	cardiopulmonary resuscitation
ED	emergency department
ETCO <sub>2</sub>	end-tidal carbon dioxide
ETT	endotracheal tube
HTA	health technology assessment
ICER	Incremental cost-effectiveness ratio
ICU	intensive care unit
PCO <sub>2</sub>	partial pressure of carbon dioxide
QALY	quality adjusted life year
RCT	randomized controlled trial
ROSC	return of spontaneous circulation
SM	standard monitoring
SpO <sub>2</sub>	arterial oxygen saturation measured by pulse oximetry

# 1 INTRODUCTION

End-tidal carbon dioxide (ETCO<sub>2</sub>) is the level of carbon dioxide that is released at the end of an exhaled breath. ETCO<sub>2</sub> levels reflect the adequacy with which CO<sub>2</sub> is carried in the blood back to the lungs and exhaled. Available evidence has established that ETCO<sub>2</sub> measurement can provide an indication of cardiac output and pulmonary blood flow.<sup>1-3</sup> Non-invasive methods for ETCO<sub>2</sub> measurement include capnometry and capnography. Capnometry provides a numerical value for ETCO<sub>2</sub>. In contrast, capnography delivers a more comprehensive measurement that is displayed in both graphical (waveform) and numerical form. For this reason, capnography is currently the most widely recommended method for monitoring ETCO<sub>2</sub><sup>4-7</sup> and will be the focus of this health technology assessment (HTA).

Capnography devices are configured as either sidestream or mainstream. In a sidestream configuration, the CO<sub>2</sub> sensor is located in the monitoring device, which is at a distance from the patient. The exhaled CO<sub>2</sub> is diverted from the airway into the device via a sampling tube of six to eight feet in length, which is attached to the breathing circuit fitted to the patient. In the case of a mainstream configuration, the CO<sub>2</sub> sensor and a sampling cell are integrated into a small device that connects directly at the airway, between the breathing circuit and endotracheal tube. Sidestream devices can monitor both intubated and non-intubated patients, while mainstream devices can be used only on intubated patients.<sup>8,9</sup> Sidestream measurement has been the most common type of ETCO<sub>2</sub> measurement modality in Canadian facilities, even as a number of new, innovative, and ultraportable mainstream capnography devices are becoming available. Whether sidestream or mainstream, capnography devices are available as hand-held portable devices or as a module or component integrated into other medical equipment, such as defibrillators, anesthesiology machines, and patient monitoring systems.

By using capnography, a patient's ventilation status is monitored in real time. Health care providers are able to identify potential breathing complications such as airway obstruction, hyperventilation, hypoventilation, or apnea, and respond accordingly with a change in clinical management (for example, providing supplemental oxygen or reassessing the patient).<sup>10-12</sup> Detecting issues at an early stage prompts timely intervention at the onset of an adverse respiratory event, which can help to avoid deterioration to a more critical, or fatal, point. A 2011 audit of major airway management complications in the United Kingdom (UK) estimated that 82% of events resulting in deaths or brain injuries in the intensive care unit (ICU) likely ensued from failure to use capnography in relevant cases.<sup>13</sup> The same audit concluded that half of the deaths that occurred in UK emergency departments could have been avoided had capnography been correctly used and interpreted.<sup>13</sup> However, if capnography is used or interpreted incorrectly, the falsely high or falsely low readings<sup>14</sup> may potentially lead to unnecessary patient interventions.<sup>15</sup> Capnography may also capture an otherwise self-resolving incident of respiratory depression,<sup>16</sup> which might also lead to unnecessary interventions.

ETCO<sub>2</sub> monitoring using capnography devices has application across several hospital and pre-hospital settings and, depending on the clinical area, the technology is at various stages of adoption. Anesthesiologists have been using capnography for decades to monitor ETCO<sub>2</sub> in patients receiving general anesthesia.<sup>17</sup> The monitoring devices help to prevent or reduce adverse events such as otherwise undetected respiratory depression and hypoxia.<sup>18-20</sup> In 2012, the Canadian Anesthesiologists' Society (CAS) updated its guidelines to make capnography part of the standard of care in the practice of anesthesia in Canada. Specifically, the CAS guidelines require continuous use of capnography in monitoring patients during general anesthesia and sedation that corresponds to levels 4 through 6 on the Ramsay Sedation Scale.<sup>6</sup> Despite strong clinical evidence for the use of capnography in general anesthesia and moderate

to deep sedation, preliminary scoping discussions suggested that there may be a low rate of access or use of this technology in Canada.

More recently, advances in both technology and scientific understanding of the value of ETCO<sub>2</sub> monitoring, particularly capnography, have expanded its use beyond anesthesiology. Capnography is also used to monitor the effectiveness of cardiopulmonary resuscitation (CPR) in patients with cardiac arrest,<sup>7,21</sup> for continuous monitoring of patients in the emergency room,<sup>10</sup> in the ICU,<sup>22,23</sup> or during ambulatory transport, and to confirm the correct placement of an endotracheal tube.<sup>23-26</sup> The American Heart Association's Advanced Cardiovascular Life Support (ACLS) guidelines, for example, now carry recommendations for the use of quantitative waveform capnography during CPR.<sup>4,27,28</sup> Emerging evidence and expert recommendations also suggest that capnography may be valuable in the early post-operative period.<sup>29-31</sup> Post-operative patients, especially those with a known history of obstructive sleep apnea or who are receiving high doses of opioids for the management of pain, are at an increased risk of adverse respiratory events. Some experts believe that monitoring ventilation with ETCO<sub>2</sub> measurement in addition to pulse oximetry could improve patient safety and post-operative clinical outcomes.<sup>30,32</sup>

## 2 THE ISSUE

The growing utility of ETCO<sub>2</sub> monitoring technology in diverse clinical settings, uncertainty regarding the clinical and cost-effectiveness of capnography devices, and access and implementation issues were the main drivers for a Health Technology Assessment (HTA).

## 3 OBJECTIVES

The objective of this HTA was to assess the clinical and cost-effectiveness of capnography (alone or in combination with other monitoring equipment) compared with no ETCO<sub>2</sub> monitoring, standard monitoring (for example, pulse oximetry, pulse rate, blood pressure, visual assessment), or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings for patients who are undergoing procedural sedation, receiving CPR, in serious or critical condition, or post-operative patients with known obstructive sleep apnea and/or receiving high opioid doses. Access and implementation issues associated with capnography were also evaluated and discussed.

### Research questions

The HTA addressed the following research questions.

#### *Clinical research questions*

1. For adult patients undergoing procedural sedation, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital settings?
2. For pediatric patients undergoing procedural sedation, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital settings?

3. For adult patients receiving CPR, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings?
4. For pediatric patients receiving CPR, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings?
5. For adult patients in serious or critical condition, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings?
6. For pediatric patients in serious or critical condition, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings?
7. For post-operative adult patients with known obstructive sleep apnea and/or who are receiving high opioid doses, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of respiration and ventilation monitoring in hospital settings?
8. For post-operative pediatric patients with known obstructive sleep apnea and/or who are receiving high opioid doses, what is the clinical effectiveness of monitoring ETCO<sub>2</sub> using capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of respiration and ventilation monitoring in hospital settings?

#### *Economic research questions*

9. For adult patients, what is the cost-effectiveness of monitoring ETCO<sub>2</sub> using capnography compared to no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in patients undergoing procedural sedation, receiving CPR, in serious or critical condition, or post-operatively with known obstructive sleep apnea and/or receiving high opioid doses in hospital or pre-hospital settings?
10. For pediatric patients, what is the cost-effectiveness of monitoring ETCO<sub>2</sub> using capnography compared to no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in patients undergoing procedural sedation, receiving CPR, in serious or critical condition, or post-operatively with known obstructive sleep apnea and/or receiving high opioid doses in hospital or pre-hospital settings?

#### *Health Services Impact*

#### **Implementation issues**

What are the implementation considerations (for example, access, training, technical support, policies, and procedures) for ETCO<sub>2</sub> monitoring using capnography in hospital and pre-hospital settings?

## 4 CLINICAL REVIEW

### 4.1 Methods

CADTH conducted a systematic review of the literature to assess the clinical effectiveness of capnography compared with no ETCO<sub>2</sub> monitoring, standard monitoring, or other forms of non-invasive respiration and ventilation monitoring in hospital or pre-hospital settings for patients who are undergoing procedural sedation, receiving CPR, in serious or critical condition, or post-operative patients with known obstructive sleep apnea and/or who are receiving high opioid doses.

#### 4.1.1 Literature search strategy

The literature search was performed by an information specialist using a peer-reviewed search strategy.

Published literature was identified by searching the following bibliographic databases: MEDLINE with in-process records & daily updates via Ovid; Embase via Ovid; The Cochrane Library (2015, Issue 7) via Wiley; and PubMed. The search strategy was comprised of both controlled vocabulary, such as the National Library of Medicine's MeSH (Medical Subject Headings), and keywords. A search for capnography and capnometry was conducted on July 31, 2015. No methodological filters were applied to limit retrieval to a study type. Where possible, retrieval was limited to the human population. Retrieval was limited to English language documents published between January 1, 2005 and July 31, 2015. Conference abstracts were excluded from the search results. See APPENDIX A for the detailed search strategies.

A search for carbon dioxide monitoring of patients undergoing CPR, or procedural sedation, or in serious or critical condition, or with obstructive sleep apnea or receiving high opioid doses post-operatively was conducted on August 12, 2015. Methodological filters were applied to limit retrieval of health technology assessments, systematic reviews, meta-analyses, randomized controlled trials, controlled clinical trials for carbon dioxide monitoring only. Where possible, retrieval was limited to the human population. Retrieval was limited to English language documents published between January 1, 2005 and August 12, 2015. Conference abstracts were excluded from the search results. See APPENDIX A for the detailed search strategies.

Regular alerts were established to update the searches until the publication of the final report. Regular search updates were performed on databases that do not provide alert services.

Grey literature (literature that is not commercially published) was identified by searching the *Grey Matters* checklist ([www.cadth.ca/grey-matters](http://www.cadth.ca/grey-matters)), which includes the websites of regulatory agencies, health technology assessment agencies, clinical guideline repositories, and professional associations. Google and other Internet search engines were used to search for additional web-based materials. These searches were supplemented by reviewing the bibliographies of key papers and through contacts with appropriate experts and industry. See APPENDIX A for more information on the grey literature search strategy.

#### 4.1.2 Selection criteria and method

The eligibility criteria for the clinical research questions (1 to 8) are reported in Table 1.

#### **Inclusion criteria**

Studies suitable for inclusion were selected from those identified through the literature search using the criteria listed below. A ten year time frame for the literature search was selected based on consensus with content experts and was believed to be sufficient given the evolving nature of the technology and its comparators. Non-randomized study designs in addition to

randomized controlled trials (RCTs) were considered for inclusion in the review because it was anticipated that due to the nature of the intervention and CADTH's interest in the evidence for safety in addition to effectiveness, there may be limited evidence in the form of RCTs.

**Table 1: Inclusion criteria for the clinical review**

	<b>Research Questions 1 &amp; 2</b>	<b>Research Questions 3 &amp; 4</b>	<b>Research Questions 5 &amp; 6</b>	<b>Research Questions 7 &amp; 8</b>
<b>Population<sup>a</sup></b>	Adult (aged ≥ 18 years) and pediatric patients who are sedated for the purposes of tolerating an interventional or diagnostic procedure. <sup>33</sup>	Adult (aged ≥ 18 years) and pediatric patients who are experiencing cardiac arrest and/or absent or abnormal breathing for which CPR is being performed. <sup>34</sup>	Adult (aged ≥ 18 years) and pediatric patients who are in serious or critical condition where vital signs are either unstable or may be unstable and are not within normal limits. <sup>35</sup>	Adult (aged ≥ 18 years) and pediatric patients receiving post-operative care with known obstructive sleep apnea and/or who are receiving high opioid doses.
<b>Intervention</b>	ETCO <sub>2</sub> monitoring using capnography (alone or in combination with other monitoring equipment)			
<b>Comparators</b>	<ul style="list-style-type: none"> <li>- No ETCO<sub>2</sub> monitoring</li> <li>- Standard monitoring (e.g., pulse oximetry, pulse rate, blood pressure, visual assessment)</li> <li>- Capnography (comparing between alternative types, such as fixed or portable)</li> <li>- Capnometry</li> <li>- Exhaled CO<sub>2</sub> detector</li> <li>- Esophageal detector device (for patients who are intubated)</li> </ul>			
<b>Outcomes</b>	<p><b>Primary clinical effectiveness outcome:</b></p> <ul style="list-style-type: none"> <li>- Detection of respiratory failure (hypoxemia or hypercapnia)</li> </ul> <p><b>Other clinical effectiveness outcomes:</b></p> <ul style="list-style-type: none"> <li>- Detection of a respiratory event (i.e., hypoventilation, hyperventilation, apnea, airway obstruction)</li> <li>- Time to detection of a respiratory event</li> <li>- Change in clinical management (i.e., re-evaluate patients, avoid</li> </ul>	<p><b>Primary clinical effectiveness outcome:</b></p> <ul style="list-style-type: none"> <li>- Survival of acute event</li> </ul> <p><b>Other clinical effectiveness outcomes:</b></p> <ul style="list-style-type: none"> <li>- Return of spontaneous circulation</li> <li>- Effectiveness of chest compressions</li> <li>- Detection of respiratory failure (hypoxemia or hypercapnia)</li> <li>- Change in clinical management (i.e., continue or withhold chest compressions, re-</li> </ul>	<p><b>Primary clinical effectiveness outcome:</b></p> <ul style="list-style-type: none"> <li>- Detection of respiratory failure (hypoxemia or hypercapnia)</li> </ul> <p><b>Other clinical effectiveness outcomes:</b></p> <ul style="list-style-type: none"> <li>- Detection of a respiratory event (i.e., hypoventilation, hyperventilation, apnea, airway obstruction)</li> <li>- Time to detection of a respiratory event</li> <li>- Change in clinical management (i.e., re-evaluate patients, provide</li> </ul>	<p><b>Primary clinical effectiveness outcome:</b></p> <ul style="list-style-type: none"> <li>- Detection of respiratory failure (hypoxemia or hypercapnia)</li> </ul> <p><b>Other clinical effectiveness outcomes:</b></p> <ul style="list-style-type: none"> <li>- Detection of a respiratory event (i.e., hypoventilation, hyperventilation, apnea, airway obstruction)</li> <li>- Time to detection of a respiratory event</li> <li>- Change in clinical management (i.e., re-evaluate patients, provide</li> </ul>

	<b>Research Questions 1 &amp; 2</b>	<b>Research Questions 3 &amp; 4</b>	<b>Research Questions 5 &amp; 6</b>	<b>Research Questions 7 &amp; 8</b>
	use of more sedative)	evaluate patients)	airway support)	airway support)
	<ul style="list-style-type: none"> <li>- Survival to hospital discharge</li> <li>- Discharge with full neurological functioning</li> <li>- Hypoxia</li> <li>- Organ damage</li> <li>- Length of stay in hospital</li> <li>- Correct placement of an endotracheal tube<sup>b</sup></li> </ul>			
	<b>Harms:</b> <ul style="list-style-type: none"> <li>- Displacement of a ventilation or intubation tube<sup>b</sup></li> <li>- Adverse events related to the capnography device (i.e., misinterpretation of capnography readings, capnography device malfunction)</li> </ul>			
<b>Study Setting</b>	Patients receiving care in hospital (emergency department, endoscopy suite, cancer ward)	Patients receiving care in hospital or pre-hospital settings. Pre-hospital settings include care provided by health care providers as first responders and during ambulatory transport		Patients receiving care in hospital
<b>Study Design</b>	Randomized controlled studies and non-randomized controlled studies (non-randomized controlled trials, quasi-experimental studies, controlled before and after studies, cohort studies, case-control studies)			

CO<sub>2</sub> = carbon dioxide; CPR = cardiopulmonary resuscitation; ETCO<sub>2</sub> = end-tidal carbon dioxide.

<sup>a</sup> Patients who may fall into more than one defined population will be included.

<sup>b</sup> For patients who are intubated.

### **Exclusion criteria**

Duplicate publications, narrative reviews, case series, case reports, editorials, and conference abstracts were excluded. Studies were excluded if they did not meet the selection criteria, took place outside of the hospital or pre-hospital setting, or if preliminary results were reported only in abstract form. If the primary objective of the study was to assess the diagnostic accuracy of capnography (for example, in detecting the correct placement of an endotracheal tube, or to assess the agreement between ETCO<sub>2</sub> and other measures of ventilation), without assessing the impact on clinical outcomes or patient management, the study was excluded. Studies were excluded if they were not published in English.

### **Selection method**

Two reviewers independently screened the titles and abstracts of all citations retrieved from the literature search. Full-text articles of the studies remaining after the initial screen were retrieved and independently reviewed based on the selection criteria. Any disagreements arising from the full-text screen were resolved through discussion, or by referral to a third party. The study selection process is presented in a PRISMA flowchart. Screening checklists used to guide study selection for research questions 1 to 8 can be found Appendix C.

#### **4.1.3 Data extraction**

Data were extracted independently by one reviewer and verified for accuracy and completeness by a second reviewer. Any disagreements were resolved through discussion, or by referral to a third party. Standardized data extraction forms were designed a priori to document and tabulate the description of the publications; relevant study characteristics; participant eligibility criteria; intervention characteristics; comparator characteristics; outcome characteristics; intervention

and comparator group characteristics; and results, including primary analysis and results of any subgroup analyses. A Microsoft Excel spreadsheet was used to manage data extraction for each question within the clinical effectiveness review. The utility of the data extraction forms was initially pilot-tested by two reviewers. In the pilot phase, the data from two studies (if available) for each of the four populations were extracted by each reviewer independently and then compared. Any disagreements were resolved through discussion until consensus was reached. Minor amendments were made to the data extraction forms during pilot testing to accommodate the extraction of important study and patient characteristics and for ease of use. Data extraction then proceeded, with one reviewer extracting all data and the second reviewer verifying all extractions. Data from figures were not used if the data points were not explicitly labeled. Data extraction forms for research questions 1 to 8 can be found in APPENDIX D.

#### *4.1.4 Outcomes and Prioritization*

For research questions 1, 2, and 5 to 8, the primary outcome was the detection of respiratory failure (i.e., hypoxemia or hypercapnia). Hypoxemia was defined according to an oxygen saturation ( $\text{SaO}_2$ ) or a partial pressure of oxygen threshold (defined, for example, as  $\text{SaO}_2 < 90\%$ ,<sup>19,36-38</sup>). All study-specific definitions of hypoxemia and hypercapnia were extracted. For research questions 3 and 4, the primary outcome was survival of the acute event. Other outcomes of interest across all populations included survival to hospital discharge, change in clinical management (e.g., continue or withhold chest compressions, re-evaluate patients), discharge with full neurological functioning (defined, for example, as cerebral performance category),<sup>39</sup> detection of a respiratory event (e.g., respiratory depression defined, for example, as  $\text{ETCO}_2 \geq 50$  mm Hg or change from baseline of  $\geq 10\%$ ;<sup>18</sup> apnea defined, for example, as decline in arterial oxygen saturation for 20 seconds),<sup>40</sup> hypoxia, return of spontaneous circulation (research questions 3 and 4), and effectiveness of chest compressions (research questions 3 and 4). While each outcome is listed as an individual measure of clinical effectiveness, it is important to recognize that each exists as part of a clinical pathway that progresses from obtaining the test information, interpreting the test information, making a patient management decision, and finally, to affecting patient health outcomes.<sup>41,42</sup> All patients experience a different path from the interpretation of test results to clinical outcomes;<sup>43</sup> therefore, the inclusion of outcomes along the entire clinical decision pathway is intended to strengthen our assessment of clinical effectiveness.<sup>41</sup>

#### *4.1.5 Quality Assessment and Risk of Bias Assessment*

One reviewer independently assessed the quality of each study, and the assessments were subsequently verified by a second reviewer. Disagreements were resolved through discussion. The Cochrane Risk of Bias tool<sup>44</sup> was used for the assessment of randomized controlled studies. For assessment of the methodological quality of non-randomized studies, the SIGN 50 checklists for cohort<sup>45</sup> and case-control studies<sup>46</sup> were used. The quality assessment was performed at the study level. No numerical scores were calculated; instead, a narrative synthesis of the quality and risk of bias assessment for each included study was conducted and is presented according to clinical research question. These summaries are accompanied by comprehensive tables that present the strengths and limitations of each study following the criteria used to conduct the critical appraisal. Studies were not excluded on the basis of the critical appraisal results.

#### *4.1.6 Data analysis methods*

A narrative synthesis of study characteristics and patient characteristics for each included study was conducted and presented according to clinical research question. These summaries were accompanied by comprehensive data tables to ensure consistency of presented information across all studies and to facilitate study comparisons by the reader. Tables were created to

summarize the study and patient characteristics separately for the randomized and non-randomized studies of each population.

Data tables were created for each outcome listed in Table 1. Due to the variability in terminology used between studies, study-specific terminology has been reported in the cells of the tables, and the definition of the outcome was reported as a corresponding footnote in the table. Each data point extracted from the included studies was categorized under the appropriate outcome heading in our review on the basis of how the outcome was measured or defined and not necessarily the term used to describe the outcome. For example, Slagelse 2013<sup>47</sup> defined hypoxia according to a pulse oximetry measure of SpO<sub>2</sub> < 92%. However, for the purposes of our review, an outcome measure based on a pulse oximetry value is indicative of hypoxemia, and would therefore be included as a data point within our primary outcome, hypoxemia.

Data were deemed sufficient for meta-analysis (i.e., low statistical and clinical heterogeneity) for two outcomes within the adult patient population undergoing procedural sedation (Research Question 1): hypoxemia and change in clinical management. Studies typically reported more than one measure of hypoxemia based on a pulse oximetry (SpO<sub>2</sub>) threshold. Outcomes deemed appropriate to pool for the clinical analysis as indicative of hypoxemia were those between a SpO<sub>2</sub> < 93% and SpO<sub>2</sub> < 90%. Severe hypoxemia was defined by SpO<sub>2</sub> measures between SpO<sub>2</sub> < 88% to SpO<sub>2</sub> < 81%. These thresholds were established based on the availability of evidence and in consultation with the clinical experts. If studies reported multiple measures of hypoxemia, measures meeting these criteria were included in the pooled analysis; all other outcomes were reported individually in a separate data table. For all other outcomes in the adult, procedural sedation population, and the remaining populations, meta-analysis was deemed inappropriate due to the limited number of studies available and the heterogeneity of the clinical and methodological characteristics of the included studies. Corresponding data tables are presented and are accompanied by a narrative synthesis to assess the direction and size of observed effects.

Meta-analyses were carried out using Cochrane Review Manager Software version 5.3 to derive pooled estimates for hypoxemia and change in clinical management. Only randomized study designs were included in the meta-analysis due to the availability of outcome data and the methodological heterogeneity between randomized and non-randomized study designs. Meta-analyses were performed using a random effects model. Forest plots were presented for all evidence syntheses to supplement reported estimates. All outcomes were dichotomous and were summarized using relative risks (RRs) and 95% confidence intervals (CIs).

Between-study heterogeneity was assessed using the I<sup>2</sup> test, with I<sup>2</sup> ≥ 70% indicating considerable heterogeneity across trials, as suggested by the *Cochrane Handbook for Systematic Reviews of Interventions*. Cochran's Q statistic (based on chi-squared, where I<sup>2</sup> = (Q-degrees of freedom)/Q) was used to test for the presence of heterogeneity based on a level of significance of 10%. Sufficient data were not available to conduct any subgroup analyses of interest identified in the review protocol (i.e., study design, setting of care, type of device, patient characteristics, and details of procedure).

Sensitivity analyses were conducted to explore the impact on pooled results of including or excluding studies based on different eligibility criteria. Specifically, two sensitivity analyses were performed based on:

1. Procedures performed (i.e., including or excluding studies with surgical abortion): Patients undergoing surgical abortion are typically young healthy females who would likely require different amounts of sedative and have different responses to the sedative

used compared to other procedures. Other studies such as those involving patients undergoing endoscopy or orthopedic procedures would include both male and female patients and may have a more diverse medical profile.

2. Differences in sedative type used (i.e., including or excluding studies using midazolam and meperidine or fentanyl): Propofol is a highly titrateable sedative that is commonly used in procedural sedation either alone or in combination with other agents. Studies that use other sedatives instead of propofol as part of their sedation regime may change the likelihood of experiencing a respiratory event.

## 4.2 Results

### 4.2.1 Quantity of research available

A total of 2753 records were identified through the initial database search. Two hundred of these articles were selected for full-text review, of which 23 were selected for inclusion in the clinical review. An additional four articles were included: one was identified through the grey literature search and three were retrieved through subsequent database alerts. The PRISMA flowchart representing the process used to identify and select studies for the review and the main reasons for exclusion can be found in APPENDIX E. The list of the excluded studies and the reasons for exclusion are provided in Table 17 of APPENDIX F.

### 4.2.2 Study characteristics

Details of the study characteristics for each research question are summarized below. Additional detail can be found in APPENDIX G.

#### 4.2.2.1 Research Question 1: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing procedural sedation

A total of six randomized and eight non-randomized studies met the inclusion criteria of the clinical review for adult patients undergoing procedural sedation (Table 1). Details of the study characteristics are provided below and in APPENDIX G.

##### 4.2.2.1.1 Country and year of publication

The publication year of the studies ranged from 2006<sup>48</sup> to 2014,<sup>19,49,50</sup> and the greatest number of studies were conducted in the USA (n=7)<sup>18,45,48,50-54</sup> followed by Germany (n=3),<sup>19,37,55</sup> with one study each from Denmark,<sup>47</sup> Japan,<sup>56</sup> the Netherlands,<sup>49</sup> and Spain.<sup>57</sup>

##### 4.2.2.1.2 Study size

Among the randomized studies, sample sizes ranged from 132 in Deitch 2010<sup>18</sup> to 760 in Beitz 2012.<sup>37</sup> For the non-randomized studies sample sizes ranged from 20<sup>55,56</sup> or 21<sup>50</sup> to up to 110 patients in Deitch 2008.<sup>53</sup>

##### 4.2.2.1.3 Study setting

All studies took place in a hospital setting, with four in the emergency room,<sup>18,48,53,54</sup> seven in the endoscopy unit,<sup>18,19,37,47,52,55,57</sup> and one in an outpatient clinic.<sup>49</sup> The hospital department setting was unclear in three studies.<sup>50,51,56</sup>

##### 4.2.2.1.4 Study design

*Randomized studies*

All randomized studies assessed the effectiveness of capnography compared to standard monitoring according to one of the following three study design schemes:

1. Standard monitoring with capnography visible versus standard monitoring alone.<sup>19,47,49</sup>
2. Standard monitoring with capnography visible versus standard monitoring with capnography not visible.<sup>18,37</sup>
3. Standard monitoring with a capnography-based signal (within 5 to 10 seconds) from an independent observer versus standard monitoring with a delayed (60 seconds) capnography signal from an independent observer.<sup>52</sup>

#### *Non-randomized studies*

Five of the eight non-randomized studies assessed the effectiveness of capnography compared to standard monitoring. These five studies were prospective cohort studies that involved patients being monitored by standard monitoring and capnography for which a research assistant or study investigator recorded the data observed by each monitoring method.<sup>48,53-55,57</sup> It was unclear if monitoring device values were visible to the treatment team in Cacho 2010.<sup>57</sup> The remaining three prospective cohort studies compared capnography to either rainbow acoustic monitoring (RAM),<sup>50</sup> or to transcutaneous capnography.<sup>51,56</sup> These studies followed a similar protocol to those that included a standard monitoring arm in that the data was either electronically or manually recorded and then retrospectively analyzed. In Tanaka 2014<sup>50</sup> all patients were monitored with RAM and capnography during their procedure. Waveform and sound files were then retrospectively analyzed and compared. In Kusinski 2012<sup>56</sup> all patients were monitored with transcutaneous capnography and ETCO<sub>2</sub> capnography, but it was unclear if the monitor values were visible to the treating team. In De Oliveria 2010,<sup>51</sup> the treating team was blinded to transcutaneous capnography data, but ETCO<sub>2</sub> capnography data was visible.

#### **4.2.2.1.5 Intervention**

The capnography devices used for ETCO<sub>2</sub> monitoring in the included studies were one of the following:

- Capnostream 20<sup>18,37,49,50,52,55</sup>
- Microcap<sup>19,56,57</sup>
- LIFEPAK 12 defibrillator/monitor<sup>48</sup>
- Capnomac Ultima<sup>51</sup>
- Nellcor Oximax NPB-75<sup>53,54</sup>
- Phillips MP20 monitor<sup>47</sup>

All devices were sidestream, multiparameter models (for example, measuring two or more of the following parameters: ETCO<sub>2</sub>, SpO<sub>2</sub>, RR, HR, ECG, temperature), connected to the patient via an oral or nasal cannula. The devices are portable, some of which being handheld (Microcap, Nellcor Oximax NPB-75), and all suitable for adult and pediatric patients. Neonatal use was specified for four of the six devices (Capnostream 20, Microcap, Nellcor Oximax NPB-75, and Philips MP20). A detailed description of the capnography devices used in the included studies can be found in Table 28 of Appendix H.

#### **4.2.2.1.6 Comparator**

##### *Randomized studies*

Standard monitoring within the randomized studies always included pulse oximetry,<sup>18,19,37,47,49,52</sup> and depending on the study and the level of detail provided for the study protocol, standard monitoring may have also included: clinical observation,<sup>19,37,47,49</sup> heart rate,<sup>19,37,47,52</sup> pulse rate,<sup>18,37</sup> blood pressure (continuous,<sup>18,47</sup> every three minutes<sup>19,37</sup> or every five minutes<sup>52</sup>) and ECG monitoring.<sup>19,37,47</sup>

RAM using the Rad-87 (Masimo Corp, software version 7805) was the comparator of interest in one study.<sup>50</sup> RAM is a non-invasive, multi-parameter bedside monitoring device that has the capacity to measure several patient parameters including: acoustic respiration rate, SpO<sub>2</sub>, pulse rate and perfusion index.<sup>58</sup>

In two studies,<sup>51,56</sup> transcutaneous capnography using the TOSCA 500 (Linde Medical Sensors AG) was the comparator of interest. Transcutaneous capnography is a non-invasive, multi-parameter portable monitoring device that has the capacity to measure several patient parameters including: transcutaneous PCO<sub>2</sub>, SpO<sub>2</sub>, and pulse rate.<sup>59</sup>

#### *Non-randomized studies*

Standard monitoring within the prospective cohort studies always included pulse oximetry,<sup>48,53-55,57</sup> and some studies also included other forms of monitoring such as: heart rate,<sup>48,55</sup> electrocardiography,<sup>55</sup> vital signs,<sup>53,54</sup> clinical observation,<sup>57</sup> and cardiac rhythm, respiratory rate, and blood pressure.<sup>48</sup>

#### **4.2.2.1.7 Outcomes measured**

Primary and secondary outcomes were explicitly identified as such in five randomized and one prospective cohort study.<sup>19,37,47,49,52,55</sup> In the remaining studies,<sup>18,48,50,51,53,54,56,57</sup> the outcomes measured were not identified as primary or secondary outcomes, but were reported as being measured. Reported outcomes included: hypoxemia,<sup>19,37,49,52,55</sup> hypoxia,<sup>47</sup> oxygen desaturation,<sup>37,55</sup> apnea,<sup>19,52,55</sup> duration of detected apnea,<sup>55</sup> bradycardia,<sup>19,37,55</sup> hypotension,<sup>37,55</sup> change in clinical management,<sup>19,37,47,49,52,55</sup> number of complications,<sup>55</sup> recovery time,<sup>37,55</sup> hypoventilation,<sup>51,57</sup> respiratory depression,<sup>53,54</sup> adverse events,<sup>53,54</sup> and clinically important acute respiratory events.<sup>48</sup>

#### **4.2.2.1.8 Statistical analysis plan**

The statistical analysis plan for the randomized studies involved an assessment of the primary outcome between intervention and comparator groups using a chi-square test,<sup>18,37,47,49,52</sup> or fisher's exact test.<sup>19</sup> All studies reported patient discontinuation from the study following randomization. Patients were excluded from the analysis due to technical device failure,<sup>49</sup> inadequate preparation for the procedure,<sup>19</sup> withdrawal of consent,<sup>37</sup> > 35% loss of data,<sup>18</sup> or a combination of factors (no data, double participation, withdrawn prior to procedure, withdrew consent, and device problems).<sup>47</sup> All studies were based on a per-protocol efficacy analysis where analyses were performed on patients who remained in the study until completion. Qadeer 2009<sup>52</sup> performed an intention-to-treat analysis for an assessment of safety outcomes. In addition to the primary analysis, multivariate regression analyses were performed as supportive analysis in three studies<sup>19,37,52</sup> to control for the following variables: age,<sup>19,52</sup> sex,<sup>52</sup> body mass index (BMI),<sup>19,52</sup> lung disease,<sup>37</sup> history of sleep apnea,<sup>19</sup> baseline oxygen saturation,<sup>37</sup> type of procedure,<sup>52</sup> and sedative dose.<sup>19,52</sup> The majority of prospective cohort studies did not perform any formal statistical analyses for an assessment of the outcomes of interest for this review.<sup>48,53,54,56,57</sup> Comparative statistical analyses on outcomes of interest for this review were performed in three studies using a chi-square test,<sup>51</sup> an exact unconditional McNemar test,<sup>55</sup> and sensitivity and specificity formulas.<sup>50</sup>

#### **4.2.2.1.9 Study funding**

Manufacturers supplied the capnography devices in four randomized studies<sup>18,37,47,52</sup> and two prospective cohort studies,<sup>48,55</sup> and a rainbow acoustic monitor in one study.<sup>50</sup> State funding was received in one study,<sup>49</sup> a university grant in another,<sup>51</sup> and no funding was specified in the remaining studies.<sup>19,48,53-57</sup>

#### **4.2.2.2 Research Question 2: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing procedural sedation**

Two randomized and two non-randomized studies met the inclusion criteria of the clinical review for pediatric patients undergoing procedural sedation (Table 1).<sup>60-63</sup> Details of the study characteristics are provided below and in APPENDIX G.

##### **4.2.2.2.1 Country and year of publication**

The studies were published in 2006,<sup>60</sup> 2007,<sup>61</sup> 2011,<sup>62</sup> and 2015.<sup>63</sup> All studies were conducted in the USA.

##### **4.2.2.2.2 Study size**

Sample sizes were generally similar between studies: 125 to 163.<sup>60-63</sup>

##### **4.2.2.2.3 Study setting**

One study took place in a pediatric emergency department of a tertiary care academic centre,<sup>63</sup> while the three other studies took place within the endoscopy unit,<sup>60</sup> imaging department,<sup>62</sup> or emergency department<sup>61</sup> of a tertiary pediatric hospital.

##### **4.2.2.2.4 Study design**

###### *Randomized studies*

The two randomized studies assessed the effectiveness of capnography compared to standard monitoring according to the following study design schemes:

1. Standard monitoring with capnography visible versus standard monitoring with capnography not visible.<sup>63</sup>
2. Standard monitoring with a capnography-based signal (> 15 seconds of an absent waveform) from an independent observer versus standard monitoring with a delayed (> 60 seconds of an absent waveform) capnography signal from an independent observer.<sup>60</sup>

###### *Non-randomized studies*

The two non-randomized studies assessed the effectiveness of capnography compared to standard monitoring. Both non-randomized studies were prospective cohort studies that involved patients being monitored by standard monitoring and capnography for which a research assistant or study investigator was present to record the data observed by each monitoring method.<sup>61,62</sup> It was unclear if monitoring device values were visible to the treatment team in Anderson 2007.<sup>61</sup>

##### **4.2.2.2.5 Intervention**

The capnography devices used for ETCO<sub>2</sub> monitoring in the included studies were one of the following:

- Nellcor Oximax NPB-75<sup>63</sup>
- Phillips MP20 monitor<sup>60</sup>
- Capnocheck II<sup>61</sup>
- N-85 hand-held capnography/pulse oximeter<sup>62</sup>

All devices were sidestream, portable, and multiparameter models (measuring two or more of parameters such as: ETCO<sub>2</sub>, SpO<sub>2</sub>, RR, HR, ECG, temperature), connected to the patient via an oral or nasal cannula. Three of the four devices were hand-held (Capnocheck II, N-85 capnograph/pulse oximeter and Nellcor Oximax NPB-75), and suitable for adult and pediatric patients. Neonatal use was specified for three of the four devices (N-85 capnography/pulse

oximeter, Nellcor Oximax NPB-75, and Philips MP20). A detailed description of the capnography devices used in the included studies can be found in Table 29 of Appendix H.

#### **4.2.2.2.6 Comparator**

Standard monitoring within the randomized studies included impedance plethysmography,<sup>63</sup> pulse oximetry,<sup>63</sup> electrocardiography,<sup>60,63</sup> vital signs (heart rate, respiratory rate, blood pressure),<sup>60,63</sup> visual assessment,<sup>60</sup> and depth of sedation.<sup>60</sup> Standard monitoring within the prospective cohort studies followed published sedation guidelines in Kannikeswaran 2011,<sup>62</sup> and involved a four member team of clinicians monitoring the patient (including vital signs and depth of sedation) in Anderson 2007.<sup>61</sup>

#### **4.2.2.2.7 Outcomes measured**

Primary and secondary outcomes were explicitly stated in the two randomized studies and included hypoventilation without hyperventilation,<sup>63</sup> staff interventions,<sup>60,63</sup> oxygen desaturations,<sup>60,63</sup> persistent hypoventilation,<sup>63</sup> timely interventions,<sup>63</sup> abnormal ventilation,<sup>60</sup> and adverse events.<sup>60</sup> Primary and secondary outcomes were not explicitly identified as such in the two prospective cohort studies, but in addition to the outcomes already stated, also measured hypoxia,<sup>62</sup> acute respiratory events,<sup>62</sup> and apnea.<sup>61</sup>

#### **4.2.2.2.8 Statistical analysis plan**

The statistical analysis plan for the randomized studies involved a comparison of the primary outcome between intervention and control groups using a chi-square test,<sup>63</sup> or fisher's exact test.<sup>60,63</sup> One study reported patient discontinuation following randomization due to crying for more than 20% of the sedation period, age, and cannula obstruction,<sup>63</sup> resulting in a per-protocol efficacy analysis. Lightdale 2006<sup>60</sup> performed an intention-to-treat analysis. In addition to the primary analysis, multivariate regression analyses were performed as supportive analysis in both studies to control for the following variables: age,<sup>60,63</sup> sex,<sup>60,63</sup> ethnicity,<sup>60,63</sup> procedure type,<sup>60</sup> duration of procedure,<sup>60,63</sup> provider,<sup>63</sup> respiratory rate,<sup>63</sup> baseline oxygen saturation and ETCO<sub>2</sub>,<sup>60</sup> use of shoulder roll at the start of the procedure,<sup>63</sup> level of sedation,<sup>60</sup> length of sedation,<sup>63</sup> and sedative dose.<sup>60,63</sup> Both prospective non-randomized studies summarized outcomes with descriptive statistics; no formal statistical analyses were conducted for the outcomes of interest for this review.<sup>61,62</sup>

#### **4.2.2.2.9 Study funding**

Manufacturers supplied the nasal cannulas in one prospective cohort study,<sup>62</sup> and the capnography filter lines and capnography device in one RCT.<sup>60</sup> A foundation clinical research grant was received in the other prospective cohort study,<sup>61</sup> and a National Institutes of Health (NIH) grant in the other RCT.<sup>63</sup>

### **4.2.2.3 Research Question 3: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing CPR**

Two non-randomized studies met the inclusion criteria of the clinical review for adult patients undergoing CPR (Table 1).<sup>64,65</sup> Details of the study characteristics are provided below and in APPENDIX G.

#### **4.2.2.3.1 Country and year of publication**

Edelson 2010<sup>64</sup> was conducted in the USA and Chen 2015<sup>65</sup> was conducted in Taiwan.

#### **4.2.2.3.2 Study size**

The sample sizes of the studies were 33 patients,<sup>64</sup> and 1113 patients.<sup>65</sup>

#### **4.2.2.3.3 Study setting**

One study included all patients who experienced an out of hospital cardiac arrest and were subsequently transferred to one of several possible settings: medical centers, regional hospitals, local hospitals, and clinics.<sup>65</sup> The other study included patients who experienced an in hospital cardiac arrest in the ICU or general ward of a tertiary care academic center.<sup>64</sup>

#### **4.2.2.3.4 Study design**

The two non-randomized studies were both observational cohort studies: one prospective cohort study,<sup>64</sup> and one retrospective cohort study.<sup>65</sup> In the prospective study, all patients were monitored with capnography and chest wall impedance for which data (for both measures) were recorded and downloaded after the resuscitation event.<sup>64</sup> In the retrospective study, a study cohort was generated from a random sample of patients covered by a national health insurance program. Patients were classified as having received ET<sub>CO</sub><sub>2</sub> or not having received ET<sub>CO</sub><sub>2</sub> and subsequently a propensity matched sample in a ratio of 1:20 was selected for the primary analysis.

#### **4.2.2.3.5 Intervention**

Patients in the prospective cohort study were monitored using the CPR-sensing monitor/defibrillator (MRx-QCPR, Philips Healthcare) with capnography recording capabilities.<sup>64</sup> This is a sidestream, portable device that is connected in line with the patient's endotracheal tube. It uses microstream technology and measures CPR quality (based on capnography and chest wall impedance) and ventilation rate. The capnography data recorded by this device was used as the intervention data.

No information was provided for the capnography device that was used in the retrospective cohort study.<sup>65</sup>

#### **4.2.2.3.6 Comparators**

The chest wall impedance data recorded by the CPR-sensing monitor/defibrillator (MRx-QCPR, Philips Healthcare) was used as the comparator data in the prospective study.<sup>64</sup> No information was provided to describe what standard monitoring consisted of in the retrospective cohort study.<sup>65</sup>

#### **4.2.2.3.7 Outcomes measured**

The primary and secondary outcomes were not explicitly stated as such in either study, however outcomes included: hyperventilation,<sup>64</sup> the percentage of time data were uninterpretable,<sup>64</sup> sustained return of spontaneous circulation,<sup>65</sup> and survival to hospital discharge.<sup>65</sup>

#### **4.2.2.3.8 Statistical analysis plan**

Statistical analysis for sensitivity and specificity of hyperventilation detection was based on a Wilcoxon signed-rank test to compare capnography to chest wall impedance in Edelson 2010.<sup>64</sup> For the retrospective study, a propensity score was used to select patients for the intervention and control group controlling for possible confounders: age, sex, year, level of urbanization, health care institute type, socioeconomic status, CPR duration and attempted defibrillation. Conditional logistic regression was then used to calculate the odds of detecting outcomes between the intervention and comparator groups.<sup>65</sup>

#### **4.2.2.3.9 Study funding**

No study specific funding source was noted in either study.<sup>64,65</sup> Authors stated that they did not have any competing interests in one study.<sup>65</sup> In the other study, authors reported to have received research funding (Philips Healthcare), research support (Laerdal Medical), speaking honoraria (Philips and Zoll Medical Corp) and employment (Laerdal Medical) by medical devices companies.<sup>64</sup>

#### **4.2.2.4 Research Question 4: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing CPR**

No studies met the inclusion criteria of the clinical review for pediatric patients undergoing CPR (Table 1).

#### **4.2.2.5 Research Question 5: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients in serious or critical condition**

Two studies, one retrospective cohort study,<sup>66</sup> and one prospective cohort study<sup>67</sup> met the inclusion criteria of the clinical review for adult patients in serious or critical condition (Table 1). Details of the study characteristics are provided below and in APPENDIX G.

##### **4.2.2.5.1 Country and year of publication**

The studies were published in 2005<sup>67</sup> and 2014,<sup>66</sup> and both were conducted in the USA.

##### **4.2.2.5.2 Study setting**

The studies took place in an emergency department: one in a tertiary care hospital,<sup>66</sup> and one in a level one trauma centre.<sup>67</sup>

##### **4.2.2.5.3 Study size**

Sample sizes were similar between studies: 153<sup>67</sup> and 169.<sup>66</sup>

##### **4.2.2.5.4 Study design**

Both studies included patients who arrived to the emergency department having been intubated out of hospital. The retrospective cohort study<sup>66</sup> undertook a chart review for patients having spent at least two hours boarding in the emergency department. Each patient was classified as having received or not received each of six individual interventions of interest, including ETCO<sub>2</sub> monitoring. The prospective cohort study<sup>67</sup> involved an assessment of patients upon arrival to the emergency department for correct placement of the endotracheal tube (ETT), method used to determine ETT position, and whether ETCO<sub>2</sub> monitoring was used in the field and upon arrival to the emergency department.

##### **4.2.2.5.5 Intervention**

No information was provided about the capnography device used in either study.<sup>66,67</sup>

##### **4.2.2.5.6 Comparators**

No information was provided to describe what standard monitoring consisted of in either study.<sup>66,67</sup>

##### **4.2.2.5.7 Outcomes measured**

In the retrospective cohort study,<sup>66</sup> the primary and secondary outcomes were not explicitly identified as such however the outcomes measured included mortality and ventilator-associated pneumonia. In the prospective cohort study,<sup>67</sup> the primary outcome was the rate of

unrecognized misplaced endotracheal tube. Other outcomes included mortality, discharge location and neurological impairment.<sup>67</sup>

#### **4.2.2.5.8 Statistical analysis plan**

In the retrospective cohort study,<sup>66</sup> the relationship between ETCO<sub>2</sub> monitoring and mortality and ventilator-associated pneumonia was assessed using a multivariate logistic regression analysis controlling for illness severity (acute and chronic). In the prospective cohort study,<sup>67</sup> the rate of unrecognized misplaced ETT was compared between patients who had ETCO<sub>2</sub> monitoring and those that did not. The statistical test performed was unclear.

#### **4.2.2.5.9 Study funding**

No funding source was disclosed for one study.<sup>66</sup> The other study stated that one study author was a consultant for the capnography manufacturer (Oridion).<sup>67</sup>

### ***4.2.2.6 Research Question 6: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients in serious or critical condition***

Two randomized<sup>68,69</sup> and one non-randomized<sup>70</sup> study met the inclusion criteria of the clinical review for pediatric patients in serious or critical condition (Table 1). One study enrolled infants who required mechanical ventilation in the delivery room or in the neonatal intensive care unit,<sup>69</sup> and two studies included infants that were preterm (<32,<sup>70</sup> or <34 weeks gestation<sup>68</sup>) or were at high risk of needing resuscitation and receiving ventilation.<sup>68</sup> Details of the study characteristics are provided below and in APPENDIX G.

#### **4.2.2.6.1 Country and year of publication**

The studies were published in 2015<sup>69,70</sup> and 2013,<sup>68</sup> taking place in Ireland,<sup>70</sup> Israel,<sup>69</sup> and the USA.<sup>68</sup>

#### **4.2.2.6.2 Study setting**

The studies were conducted in a university maternity hospital,<sup>70</sup> a labour and delivery unit of a medical centre,<sup>68</sup> and the neonatal intensive care unit of a university-affiliated tertiary care centre.<sup>69</sup>

#### **4.2.2.6.3 Study size**

Sample sizes were 92 in the non-randomized study,<sup>70</sup> and 50,<sup>68</sup> and 66,<sup>69</sup> in the randomized studies.

#### **4.2.2.6.4 Study design**

In Kong 2013,<sup>68</sup> infants in the intervention arm were monitored with capnography and the resuscitation team was told to keep ETCO<sub>2</sub> levels between 40 mmHg and 55 mmHg. In the control group, the ETCO<sub>2</sub> monitor display was covered and the resuscitation team was told to adjust ventilation as required according to their clinical judgement. The treatment team in the other randomized controlled trial used the capnography data to guide patient care; however no target ETCO<sub>2</sub> level was prescribed. In the control group, the ETCO<sub>2</sub> data was covered, but the capnography tracing was visible to the treatment team to ensure adequate measurements and to indicate when a change to the sampling line was required.<sup>69</sup> In the prospective cohort study,<sup>70</sup> all infants in the intervention group were monitored with capnography as soon as they were placed on the resuscitation table. The treatment team was told to obtain capnography waveforms but to not change patient management based on the numeric (capnometry) values. The comparator group was a historical cohort that was not monitored with capnography.<sup>70</sup>

#### **4.2.2.6.5 Intervention**

The capnography devices used for ETCO<sub>2</sub> monitoring in the included studies were one of the following:

- NICO Respiratory Profile Monitor<sup>68</sup>
- Philips Intellivue monitor<sup>70</sup>
- Capnostream 20p<sup>69</sup>

The NICO respiratory profile monitor was a mainstream, multiparameter model that used a PediCap device to detect carbon dioxide levels. The remaining two devices were sidestream, portable, and multiparameter models (measuring two or more of parameters such as: ETCO<sub>2</sub>, SpO<sub>2</sub> and RR) and was connected to the patient via a sampling line. A detailed description of the capnography devices used in the included studies can be found in Appendix H.

#### **4.2.2.6.6 Comparators**

In one RCT,<sup>68</sup> full details of the monitoring available for the comparator group was unknown, however pulse oximeters were used for all patients, and it was stated that ventilation was provided based on clinical assessment for the control group.<sup>68</sup> No information was provided to describe what standard monitoring consisted of for the historical control group in Hawkes 2015,<sup>70</sup> or the masked control group in Kugelman 2015.<sup>69</sup>

#### **4.2.2.6.7 Outcomes measured**

In the two randomized studies, the primary outcome was related to whether a patient was within a target range for the partial pressure of carbon dioxide (PCO<sub>2</sub>). In one study, the primary outcome was measured as the number of patients within a PCO<sub>2</sub> range of 40 mmHg to 60 mmHg upon admission to the ICU (approximately one hour after birth),<sup>68</sup> and in the other study, it was measured as the percentage of time spent in a safe PCO<sub>2</sub> range of 30 mmHg to < 60 mmHg.<sup>69</sup> Secondary outcomes were not explicitly identified in one study,<sup>69</sup> but the other study included duration of ventilation, and adjustment of ventilation variables.<sup>68</sup> Other outcomes measured in Kugelman<sup>69</sup> included the number of arterial blood gas measurements, the number of chest radiographs, duration of mechanical ventilation and length of stay.<sup>69</sup> In the non-randomized study, the outcomes measured included the number of patients intubated and the percentage of patients within the target PCO<sub>2</sub> range (5 kPa to 8 kPa).<sup>70</sup>

#### **4.2.2.6.8 Statistical analysis plan**

In the randomized studies, the primary outcome was assessed using the chi-squared test,<sup>68</sup> and an unpaired two sample t test.<sup>69</sup> In Hawkes 2015,<sup>70</sup> the percentage of patients within the PCO<sub>2</sub> target range was compared between the capnography group and the historical control group using Fisher's exact test.<sup>70</sup>

#### **4.2.2.6.9 Study funding**

Manufacturers provided the devices and sampling lines in one study.<sup>69</sup> A foundation research award and fellowship supported the prospective cohort study.<sup>70</sup> No funding source was reported in one study and authors stated that there were no conflicts of interest.<sup>68</sup>

### ***4.2.2.7 Research Question 7: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients with known obstructive sleep apnea or receiving high-doses of opioids in post-operative care***

Two studies met the inclusion criteria of the clinical review for adult patients being monitored in a post-operative setting (Table 1): one randomized study<sup>31</sup> and one prospective cohort study.<sup>71</sup> Details of the study characteristics are provided below and in APPENDIX G.

#### **4.2.2.7.1 Country and year of publication**

The studies were published in 2008,<sup>31</sup> and 2013,<sup>71</sup> and both were conducted in the USA.

#### **4.2.2.7.2 Study setting**

Both studies took place in a hospital post-anesthesia care unit, one of which being an academic tertiary care facility.<sup>71</sup>

#### **4.2.2.7.3 Study size**

Fifty-four patients were included in the randomized study,<sup>31</sup> and 33 patients were included in the prospective cohort study.<sup>71</sup>

#### **4.2.2.7.4 Study design**

Hutchison 2008<sup>31</sup> randomized patients to either the intervention group, which included all patients being continuously monitored with capnography, or a control group where patients were monitored every four hours by observation or auscultation using pulse oximetry and respiratory rate. In Ramsay 2013<sup>71</sup> all patients in the retrospective cohort were monitored with rainbow acoustic monitoring and capnography for which data were retrospectively reviewed and compared to manually annotated data. The reference method (manual annotation) consisted of the use of the acoustic and capnography data (as well as breathing sounds) annotated by a trained technician.

#### **4.2.2.7.5 Intervention**

The capnography devices used for ETCO<sub>2</sub> monitoring in the included studies were one of the following:

- Capnostream 20<sup>71</sup>
- Alaris ETCO<sub>2</sub> module<sup>31</sup>

Both devices are mainstream, multiparameter models (measuring two or more of parameters such as: ETCO<sub>2</sub>, SpO<sub>2</sub>, RR and FiO<sub>2</sub>) connected to the patient via a nasal cannula,<sup>31</sup> or a Smart CapnoLine.<sup>71</sup> The Capnostream is a portable stand-alone device, while the Alaris ETCO<sub>2</sub> module is an add-on to the Alaris monitoring system. A detailed description of the capnography devices used in the included studies can be found in Appendix H.

#### **4.2.2.7.6 Comparators**

Full details of the monitoring available for the comparator group is unknown, however pulse oximetry and respiration rate (by observation and auscultation) was monitored.<sup>31</sup> The comparator device in Ramsay 2013<sup>71</sup> was a pulse CO-Oximeter with rainbow acoustic monitoring technology. Respiratory rate was measured using a bioacoustics sensor applied to the patient's neck.<sup>71</sup>

#### **4.2.2.7.7 Outcomes measured**

In the randomized study,<sup>31</sup> the primary outcome was respiratory depression and secondary outcomes included pauses in breathing during sleep, time in the post-anesthesia care unit, and morphine consumed.<sup>31</sup> In the non-randomized study,<sup>71</sup> primary and secondary outcomes were not explicitly identified as such, however measured outcomes included: respiratory pause, and the percentage of time the device provided data.<sup>71</sup>

#### **4.2.2.7.8 Statistical analysis plan**

In the randomized study,<sup>31</sup> no formal statistical analyses were conducted for the outcomes of interest for this review. In the non-randomized study,<sup>71</sup> the comparative effectiveness of the devices with respect to sensitivity of detecting a respiratory pause was assessed statistically using Fisher's exact test.

#### **4.2.2.7.9 Study funding**

Funding for the research personnel who collected the study data and provided the equipment was provided by the device manufacturer in one study.<sup>71</sup> The authors of this study also received manufacturer funding, and one author was employed by the company.<sup>71</sup> In the other study, the manufacturer supplied the devices, and provided an honorarium to one of the study authors for speaking at a convention.<sup>31</sup>

#### **4.2.2.8 Research Question 8: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care**

No studies met the inclusion criteria of the clinical review for pediatric patients being monitored in a post-operative setting (Table 1).

#### **4.2.3 Patient characteristics**

Details of the patient characteristics for each research question are summarized below. Additional detail can be found in APPENDIX I.

##### **4.2.3.1 Research Question 1: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing procedural sedation**

Fourteen (six randomized<sup>18,19,37,47,49,52</sup> and eight non-randomized<sup>48,50,51,53-57</sup>) studies included adult patients undergoing procedural sedation. The mean and median ages of the participants in the included studies were primarily older than 50 years<sup>19,37,50,52,55-57,72</sup> and ranged from 24 years<sup>49</sup> (patients were primarily undergoing surgical abortion) to 62.5 years<sup>55</sup> (patients were all undergoing percutaneous transhepatic cholangiodrainage). Two of the studies included both adult and pediatric patients,<sup>48,54</sup> but are included in this review for the adult population because the majority of patients were adults (median age 38 years,<sup>48</sup> 85% adult<sup>54</sup>). Two studies<sup>49,51</sup> included only female patients, and the others ranged from a population that was 25%<sup>50</sup> to 90%<sup>56</sup> male, with the majority of the studies being between 40% and 60% male.<sup>18,19,37,48,52-55,57,72</sup>

Mean body mass index (BMI) was reported in the majority of included studies<sup>19,37,49-52,55,72</sup> and ranged from just over 23 kg/m<sup>2</sup> to 31.6 kg/m<sup>2</sup>.<sup>49,50</sup> Smoking status and comorbid conditions were poorly reported. A minority of studies reported smoking status,<sup>19,37,52,55,57</sup> or more than one comorbid condition.<sup>19,37,55,57</sup> The percentage of current or former smokers ranged from 22<sup>57</sup> to 45,<sup>37</sup> and the percentage of patients with cardiovascular or heart disease ranged from 16<sup>57</sup> to 38.<sup>19</sup>

The type of procedure for which patients were being sedated was not reported in one study.<sup>51</sup> In the remaining studies, patients underwent the following procedures, with some studies including patients undergoing one of several possible procedure types:

- fracture reduction or joint reduction (N = 5)<sup>5,18,48,53,54</sup>
- colonoscopy (N=3)<sup>19,37,57</sup>

- upper or lower endoscopy (N = 3)<sup>47,52,56</sup>
- abscess and incision drainage(N = 3)<sup>18,53,54</sup>
- surgical abortion (N = 1)<sup>49</sup>
- knee replacement (N = 1)<sup>50</sup>
- percutaneous transhepatic cholangiodrainage (N = 1)<sup>55</sup>

Two studies did not report the type or dose of sedative used.<sup>50,51</sup> In the remaining studies, patients received one of several possible types of sedatives, including:

- propofol (N = 9)<sup>18,19,37,47-49,53,55,57</sup>
- propofol with alfentanil (N = 1)<sup>49</sup>
- propofol with midazolam and/or ketamine (N = 1)<sup>19</sup>
- propofol with fentanyl and midazolam (N = 1)<sup>57</sup>
- midazolam with meperidine or fentanyl (N = 2)<sup>52,54</sup>
- midazolam (N = 3)<sup>48,55,56</sup>
- pentazocine (N = 1)<sup>56</sup>
- petidine with midazolam (N = 1)<sup>57</sup>
- etomidate (N = 1)<sup>48</sup>
- ketamine (N = 1)<sup>48</sup>

Procedure lengths varied from less than 20 minutes<sup>18,49</sup> to 174 minutes.<sup>56</sup> Six studies did not report the length of the procedures.<sup>48,50,51,53-55</sup> and of those reported, the procedure length generally lasted between 20 and 40 minutes.<sup>19,37,47,52,57</sup> In most studies the provision of supplemental oxygen was part of routine care during the procedures.<sup>18,19,37,47,48,50,51,55-57</sup>

The depth of sedation was generally poorly reported, with five studies reporting a mean or median Ramsay Sedation Score (RSS) of  $\geq 4$ ,<sup>18,49,51,53,54</sup> and one reporting the percentage of patients were under “deep sedation” (92% in the intervention arm and 94% in the comparator arm; defined as the patient being unable to respond to verbal commands or to react to endoscopic maneuvers).<sup>19</sup> Most studies reported an American Society of Anesthesiologists (ASA) class for the participating patients, and of those studies, only one study included patients of an ASA class > III (Schlag 2013<sup>55</sup> one patient with ASA class IV).<sup>19,37,47,49,52,55-57</sup> An ASA score of I to III indicates that patients were either healthy or had non-life-threatening mild or severe systemic disease prior to their procedure.<sup>73</sup>

#### **4.2.3.2 Research Question 2: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing procedural sedation**

Four (two randomized<sup>60,63</sup> and two non-randomized<sup>61,62</sup>) studies included pediatric patients undergoing procedural sedation. Three studies had a mean or median age  $\leq 10$  years old<sup>61,63,74</sup> and one study had a median age just over 14 years old.<sup>60</sup> One study did not report the percentage of male or female patients<sup>61</sup> and the remaining three populations were more than 50% male.<sup>60,62,63</sup> BMI and comorbid conditions were not reported in any of the four studies. The studies included patients undergoing the procedures listed below, with some studies including patients undergoing one of several possible procedure types:

- fracture reduction (N = 2)<sup>61,63</sup>
- endoscopy (N = 1)<sup>60</sup>
- colonoscopy (N = 1)<sup>60</sup>
- joint reduction (N = 1)<sup>61</sup>
- laceration repair (N = 1)<sup>63</sup>

- incision and drainage of abscess (N = 1)<sup>63</sup>
- brain MRI (N = 1).<sup>62</sup>

The types of sedative used during the procedures are listed below, with some study protocols including a range of sedatives:

- midazolam (N = 3)<sup>60,62,63</sup>
- fentanyl (N = 2)<sup>60,62</sup>
- ketamine (N = 1)<sup>63</sup>
- phenobarbital (N = 1)<sup>62</sup>
- chloral hydrate (N = 1)<sup>62</sup>
- propofol (N = 1).<sup>61</sup>

Procedure length was not reported in the two non-randomized studies<sup>61,62</sup> Of the two RCTs, mean procedure length was 10 minutes (patients who underwent endoscopy) in one study,<sup>60</sup> and a mean of 39 minutes (patients receiving colonoscopy) in the other study.<sup>60</sup> Routine administration of supplemental oxygen occurred in one study.<sup>60</sup>

Depth of sedation was reported in two of the studies.<sup>60,61</sup> Ramsay sedation scores (RSS) ranged between two and four in Lightdale 2006,<sup>60</sup> and the median RSS was six (range three to eight) in Anderson 2007.<sup>61</sup> Three studies included patients with an ASA score of I and II<sup>60-62</sup> indicating that patients were either healthy or had mild systemic disease, and one study included patients with an ASA score of I, II and III indicating that patients were included even if they had non-life-threatening severe systemic disease (ASA class III).<sup>63,73</sup>

#### **4.2.3.3 Research Question 3: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing CPR**

Two included studies examined adult patients requiring CPR.<sup>64,65</sup> The Edelson prospective study<sup>64</sup> included 33 patients who had a mean age of 59 years (range 19 to 87 years), 63.6% of whom were male, and 100% of whom were intubated. The mean number of minutes per arrest was 11.3. The Chen retrospective study examined 1,113 patients (53 in the ETCO<sub>2</sub> group and 1,060 in the propensity matched cohort; 50.9% male in the ETCO<sub>2</sub> group and 60.8% male in the matched cohort) with a mean age >68 years in both groups.<sup>65</sup> Approximately 71% of patients in each group had some form of cardiovascular disease and the mean number of minutes CPR performed was 25 (ETCO<sub>2</sub>) and 27 (control) minutes.<sup>65</sup>

#### **4.2.3.4 Research Question 4: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing CPR**

No studies met the inclusion criteria of the clinical review for pediatric patients undergoing CPR.

#### **4.2.3.5 Research Question 5: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients in serious or critical condition**

The retrospective study examining adults in serious or critical condition reported limited details on the patient characteristics.<sup>66</sup> The prospective study that included adult and pediatric patients in serious or critical condition was primarily comprised of adults; however the exact number of pediatric patients was not explicitly stated in the study report. The mean age of patients was older than 40 years.<sup>67</sup> Most were male (69.9%) trauma patients (78%) and all patients were intubated.

#### **4.2.3.6 Research Question 6: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients in serious or critical condition**

Two randomized<sup>68,69</sup> and one non-randomized<sup>70</sup> study examining pediatric patients in serious or critical condition were included. All studies included preterm infants (mean or median gestational age <30 weeks in all studies) and two of the studies (the Kong RCT<sup>68</sup> and the Hawkes non-randomized study<sup>70</sup>) were comprised of at least 60% male infants (the Kugelman RCT<sup>69</sup> did not report the sex of the study infants) The sample sizes were 50<sup>68</sup> and 66<sup>69</sup> in the two RCTs and 92<sup>70</sup> in the non-randomized study. The minority of infants were intubated in the non-randomized study<sup>70</sup> (<32%), 52% of the infants were intubated in the Kong RCT,<sup>68</sup> and all patients were intubated in the Kugelman study.<sup>69</sup>

#### **4.2.3.7 Research Question 7: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients with known obstructive sleep apnea or receiving high-doses of opioids in post-operative care**

One randomized<sup>31</sup> and one non-randomized study<sup>71</sup> examining adult patients receiving care in the post-operative setting were included. The procedures performed were orthopedic (i.e., knee and hip replacement, shoulder repair) in the randomized study<sup>31</sup> and primarily gastrointestinal surgeries, including gastric bypass, gastric sleeve, in the non-randomized study.<sup>71</sup> The mean age of patients in the randomized study<sup>31</sup> was older than 60 years and in the non-randomized study<sup>71</sup> was a mean of 45 years. Mean BMI was <35 kg/m<sup>2</sup>,<sup>31</sup> and >40 kg/m<sup>2</sup>,<sup>71</sup> Sleep apnea was an exclusion criteria in the randomized study<sup>31</sup> and at least 40% of patients in the non-randomized study had sleep apnea.<sup>71</sup> Almost all of the patients (100%<sup>31</sup> and 97%<sup>71</sup>) in both studies were prescribed post-operative pain medication.<sup>31,71</sup>

#### **4.2.3.8 Research Question 8: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care**

No studies met the inclusion criteria of the clinical review for pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care.

#### **4.2.4 Quality Assessment and Risk of Bias Assessment**

Details of the quality assessment and risk of bias assessment for each research question are summarized below. Additional detail for each study can be found in APPENDIX J.

##### **4.2.4.1 Research Question 1: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing procedural sedation**

All RCTs had adequate sequence generation and allocation concealment except for one study,<sup>49</sup> where there was insufficient information to judge the adequacy of allocation concealment. Due to the nature of the intervention, blinding of the treatment team and outcome assessors was not possible in most cases except for Qadeer<sup>52</sup> where the treatment team was blind to patient allocation, and Deitch 2010<sup>18</sup> where the study investigators assessed each graph for the outcomes measured (i.e., hypoxia and respiratory depression) prior to study blinding being broken. In two studies, patients were excluded if they had missing data,<sup>47</sup> or had >35% missing data,<sup>18</sup> so any potential differential in missing data between the intervention and control groups is unknown. In the remaining studies, the reasons for attrition were

described,<sup>19,37,49,52</sup> and were minimal, with no apparent differential between study groups. The risk of selective reporting was minimal among the studies with a clinicaltrials.gov record,<sup>19,37,47,49,52</sup> as the outcomes listed in the registry were aligned with the outcomes reported in the articles. Other concerns related to study quality include the potential for two studies being underpowered,<sup>18,49</sup> and in one study,<sup>37</sup> baseline differences in patient characteristics between groups suggesting potential problems with randomization despite adequate randomization and concealment (the baseline differences between groups were adjusted for in the analysis).<sup>37</sup>

All prospective cohort studies included patients who were monitored by both capnography and the comparator, so there is no concern with differential selection of patients between an intervention and control group. Study investigators who were responsible for recording patient data during the procedure (i.e., ETCO<sub>2</sub>, SpO<sub>2</sub>, clinical observations) were not blinded to each monitoring modality; it is possible that the interpretation of one set of monitoring data would influence the interpretation of another set, particularly for subjective outcomes, potentially resulting in a decreased likelihood of finding a difference between the methods of monitoring within a given study. There was no indication of selective reporting in one study that had a protocol available,<sup>51</sup> and the extent of selective reporting in the remaining studies is unknown. Furthermore, primary and secondary outcomes were not explicitly stated in all studies except one.<sup>55</sup> The number of patients who were approached for the study and subsequently accepted and enrolled was poorly reported in all studies except De Oliveira 2010 where all but one individual agreed to participate.<sup>51</sup> Studies reported either minimal or no patients being lost to follow-up;<sup>48,50,51,53-55</sup> otherwise, there was no mention of whether or not missing data was present.<sup>56,57</sup> All studies demonstrated an acceptable effort to minimize bias (i.e., most checklist criteria were met), except for one study<sup>57</sup> for which the reporting was inadequate to comment on the extent to which biases were or could have been minimized. The designs of each study make them particularly susceptible to biases: Schlag 2013<sup>55</sup> was not intended to be an interventional study, two studies were not designed to assess the effectiveness of ETCO<sub>2</sub> monitoring,<sup>53,54</sup> Burton 2006<sup>48</sup> was terminated prematurely based on an interim safety analysis, and Tanaka 2014<sup>50</sup> was classified as a pilot study with 20 patients enrolled.

#### **4.2.4.2 Research Question 2: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing procedural sedation**

The two RCTs had adequate sequence generation and allocation concealment. Given the nature of the study design, patients and physicians were blinded to patient treatment arm in Lightdale 2006 (physicians were signaled by an independent investigator if hypoventilation was detected by the capnography device for > 15 seconds in the intervention arm and > 60 seconds in the control arm);<sup>60</sup> but blinding was not possible in Langhan 2015,<sup>63</sup> where capnography was either visible or not visible to the treatment team. Outcome assessors were not blinded to patient allocation in either study. Other potential study quality concerns include an outdated pulse oximetry device in one study,<sup>60</sup> and the potential for inadequate power in the other study.<sup>63</sup>

In the two prospective cohort studies, patients were monitored by both capnography and the comparator, so there is no concern with differential selection of patients between an intervention and control group. However, both studies recruited patients based on a convenience sample limited to the availability of the research assistant, so selection bias is a concern. Selection bias may be particularly problematic in Kannikeswaran 2011<sup>62</sup> where patients were excluded from the study due to ETCO<sub>2</sub> device malfunction (n = 10; 5%) or nasal cannula dislodgement (n = 12; 6%). This exclusion may lead to results in favor of the capnography because these intervention failures are not considered in the analysis. In both studies, the research assistants who were

responsible for recording patient data during the procedure (i.e., ETCO<sub>2</sub>, airway events and interventions) were not blinded to each monitoring modality. It is possible that the interpretation of one set of monitoring data would influence the interpretation of another set, particularly for subjective outcomes (for example, adverse or acute airway events defined by clinical observation criteria), potentially resulting in a decreased likelihood of finding a difference between the methods of monitoring within a given study. Study methodology was not described in detail in Anderson 2007<sup>61</sup> – it is uncertain if the treating team could see the ETCO<sub>2</sub> readings.

#### ***4.2.4.3 Research Question 3: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing CPR***

The prospective cohort study<sup>64</sup> included a series of resuscitation events from patients that were monitored by both capnography and chest wall impedance, so there is no concern with differential selection of patients between an intervention and control group. However, of the eligible events, 61% (58 of 95) were excluded due to incomplete outcome data, so attrition bias is a concern. It is unclear if these events were excluded due to missing data from capnography, chest wall impedance, or another measure. Although sensitivity and specificity outcomes (from which we derived our true positives data) were based on comparison to a study-defined gold standard, it is possible the sensitivities are overstated because the gold standard was based on hyperventilations that were detected by capnography and chest wall impedance and not a measure independent of the devices used in the study.

The retrospective cohort study<sup>65</sup> included patients from an insurance claims database who were classified as having received ETCO<sub>2</sub> or not received ETCO<sub>2</sub>. Patients in the intervention and the control groups were selected from the same cohort of patients, with the control group being selected based on propensity score matching with the intervention group. Patients were selected as having an out of hospital cardiac arrest based on international classification of diseases (ICD) codes for ventricular fibrillation, cardiac arrest, and sudden death. The authors do not present a comparison of the number of cases for each indication (by ICD code) between cases and controls. It is possible that there were differences in the proportion of patients with each indication between cases and controls, and therefore a systematic difference between the rate of exposure and outcome between the two groups. The authors recognize that the measurement of exposure status (i.e., the use of ETCO<sub>2</sub>) may not have been recorded and billed in all cases. The presence of incorrect classification of exposure status is likely to bias the result in the direction of no effect. Hospital admission was used as a surrogate for return of spontaneous circulation (ROSC), and due to the reliance on clinical records, survival to hospital discharge was known only if it was recorded in the patient's chart. The study authors did not discuss the validity of these assumptions, and it is unclear if there would be a relationship between the documentation of these outcomes and a patient's exposure status.

#### ***4.2.4.4 Research Question 4: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing CPR***

No studies met the inclusion criteria of the clinical review for assessing capnography for pediatric patients undergoing CPR.

#### ***4.2.4.5 Research Question 5: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients in serious or critical condition***

Two studies had key limitations that made it difficult to suggest a clear association between the use of capnography and the outcomes measured (i.e., mortality and ventilator associated

pneumonia,<sup>66</sup> and unrecognized misplaced ETT<sup>67</sup>). In the retrospective chart review,<sup>66</sup> there was a limited number of patients who were monitored with capnography (5.9%, N=169) suggesting an underpowered study, and the authors made no conclusions specific to the value of capnography monitoring. In Silvestri 2005,<sup>67</sup> patients were assessed for the primary outcome (i.e., rate of unrecognized misplaced ETT) upon enrollment. Exposure status was subject to recall bias as it was retrospectively assessed using self-report by the treatment team, and may have been influenced by knowledge of the primary outcome.

#### **4.2.4.6 Research Question 6: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients in serious or critical condition**

Selection bias was minimized in two studies with appropriate randomization and allocation concealment in Kong 2013<sup>68</sup> and the selection of a historical control group with similar characteristics in Hawkes 2015.<sup>70</sup> It is unclear in Kong 2013<sup>68</sup> who was responsible for recording study outcome data and if they were blind to patient allocation. Similarly, the type of standard monitoring equipment used by clinicians in the historical cohort in Hawkes 2015<sup>70</sup> is unknown. Hawkes 2015<sup>70</sup> was also not designed to assess the impact of ETCO<sub>2</sub> monitoring on patient outcomes, and therefore may have been inadequately powered with limited data on potential confounders.

There were several key methodological concerns in Kugleman 2015.<sup>69</sup> The method of randomization and allocation was unclear, patients and the treatment team were not blind to patient allocation, and it is unclear who was responsible for measuring the primary outcome and whether they were blind to patient allocation. Additionally, there was an imbalance in the number of patients with missing data due to technical problems between the groups (6/25, 24% in the intervention group; 2/30, 7% in the control group), and the results for the primary outcome were not reported. The greater number of patients with missing data in the intervention group may bias the results in favour of the capnography group because these intervention failures are not considered in the analysis. There is insufficient reporting of study methods to adequately assess the direction of the remaining biases.

#### **4.2.4.7 Research Question 7: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients with known obstructive sleep apnea or receiving high-doses of opioids in post-operative care**

Hutchison 2008<sup>31</sup> was particularly limited by lack of reporting of several methodological criteria for assessing risk of bias including their randomization procedure, efforts for allocation concealment, blinding, and the existence and handling of missing data. Additionally, the results of the study indicate that all respiratory events were detected by respiratory rate changes or apnea detection and not by pulse oximetry or capnography, suggesting that there may be something else other than the devices that are detecting events differentially between the groups. Ramsay 2013<sup>71</sup> included a cohort of patients who were monitored by both capnography and rainbow acoustic monitoring, so there is no concern with differential selection of patients between an intervention and control group. Although the detection of a respiratory event was based on a comparison to a reference that was evaluated by a trained technician and confirmed by a second technician, it is possible that the number of events is overstated because the reference was based on respiratory pauses that were detected by capnography and rainbow acoustic monitoring and not an independent measure.

#### **4.2.4.8 Research Question 8: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care**

No studies met the inclusion criteria of the clinical review for assessing capnography for pediatric patients being monitored in a post-operative care setting.

#### **4.2.5 Data analysis and synthesis**

##### **4.2.5.1 Research Question 1: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing procedural sedation**

###### **4.2.5.1.1 Primary clinical effectiveness outcome**

*Detection of respiratory failure: hypoxemia*

###### **Capnography versus standard monitoring**

A measure of hypoxemia was reported in six RCTs<sup>18,19,37,47,49,52</sup> and one prospective cohort study.<sup>55</sup> The pooled analysis included outcomes reported in the RCTs. The prospective cohort study,<sup>55</sup> was a non-interventional study that measured the number of hypoxemia events predicted by capnography versus those predicted by clinical observation, and was therefore deemed inappropriate to pool with the interventional RCTs. The pooled results found a statistically significant reduced risk of detecting hypoxemia (SpO<sub>2</sub> < 93% to SpO<sub>2</sub> < 90%) in the intervention group (capnography with standard monitoring) versus the comparator group (standard monitoring alone). The risk of experiencing hypoxemia was approximately one-third less likely (RR 0.68, 95% CI 0.56 to 0.82) in the intervention group versus the comparator group (Table 2). The I<sup>2</sup> measure for heterogeneity was 42% indicating that there may be moderate heterogeneity between studies.<sup>75</sup> Clinical (i.e., different procedure types, sedation levels, length of procedure, and patient characteristics such as BMI, smoking status and co-morbid conditions) and methodological (i.e., type of comparator, the clinician performing the sedation, definition of hypoxemia, and how patients with missing data were handled) characteristics of the included studies were actively explored as likely sources of the heterogeneity found in this analysis. Individual study data and the forest plot can be found in Table 55 and Figure 6, respectively of APPENDIX K.

Two sensitivity analyses were performed to assess the robustness of findings to the inclusion of studies with different characteristics:

1. Excluding van Loon 2014,<sup>49</sup> due to differences in patient characteristics (all female, young, and otherwise healthy patients) resulting from the type of procedure performed (i.e., surgical abortion).
2. Excluding Qadeer 2009<sup>52</sup> due to differences in sedative type used (i.e., patients were sedated with midazolam and meperidine or fentanyl).

A statistically significant reduced risk of detecting hypoxemia was maintained in the intervention group versus the comparator group when van Loon 2014<sup>49</sup> was excluded from the analysis, although the RR is lower than in the main analysis (RR 0.62, 95% CI 0.54 to 0.72, I<sup>2</sup> = 0%) (Table 2). A statistically significant reduced risk, of the same order of magnitude, of detecting hypoxemia was also maintained in the intervention group versus the comparator group when Qadeer 2009<sup>52</sup> was excluded from the analysis (RR 0.68, 95% CI 0.52 to 0.88, I<sup>2</sup> = 54%) (Table 2).

**Table 2: Pooled analysis for the detection of respiratory failure (hypoxemia) for adults undergoing procedural sedation (RCTs, random effects model)**

Hypoxemia (SpO <sub>2</sub> < 93% to SpO <sub>2</sub> < 90%)	Standard monitoring + capnography		Standard monitoring		Effect estimate and measure of heterogeneity			
	Events	Total	Events	Total	RR	95% CI	I <sup>2</sup>	
<b>Primary analysis</b> (Total number of patients = 2624)								
Randomized studies (n=6)	239	1311	352	1313	0.68	0.56	0.82	42%
<b>Sensitivity analyses</b>								
Excluding van Loon 2014 <sup>49</sup> (n=5) <sup>a</sup>	186	1105	300	1104	0.62	0.54	0.72	0%
Excluding Qadeer 2009 <sup>52</sup> (n=5) <sup>b</sup>	182	1187	267	1190	0.68	0.52	0.88	54%

CI = confidence interval; RCT = randomized controlled trial; RR = risk ratio; SpO<sub>2</sub> = arterial oxygen saturation measured with pulse oximetry

<sup>a</sup>Limited to studies with patients undergoing clinically similar procedures.

<sup>b</sup>Limited to studies that use propofol alone or propofol in combination with other drugs for sedation.

### *Detection of respiratory failure: severe hypoxemia*

#### **Capnography versus standard monitoring**

A measure of severe hypoxemia (SpO<sub>2</sub> < 88% to SpO<sub>2</sub> < 81%) was reported in five of the six RCTs<sup>19,37,47,49,52</sup> and none of the prospective cohort studies.<sup>48,50,51,53-57</sup> The pooled analysis included outcomes reported in the RCTs. There was a lower risk of detecting severe hypoxemia in the intervention group (capnography with standard monitoring) versus the comparator group (standard monitoring alone) (RR 0.70, 95% CI 0.48 to 1.02), however, this result was not statistically significant. There was evidence for moderate or substantial heterogeneity between studies (Chi<sup>2</sup> = 7.94, df = 4, P=0.09; I<sup>2</sup> = 50%).<sup>75</sup> (Table 3). In addition to the likely sources of heterogeneity described above for hypoxemia, there were also a fewer number of studies and a wider variation in the definition of severe hypoxemia for this analysis compared to the measure of hypoxemia. Detailed outcome data and a forest plot can be found in Table 55 and Figure 7 respectively of APPENDIX K. Two sensitivity analyses were performed to assess the robustness of findings:

1. Excluding van Loon 2014<sup>49</sup> due to differences in patient characteristics (all female, young, and otherwise healthy patients) resulting from the type of procedure performed (i.e., surgical abortion).
2. Excluding Qadeer 2009<sup>52</sup> due to differences in sedative type used (i.e., patients were sedated with midazolam and meperidine or fentanyl).

A non-statistically significant difference in experiencing severe hypoxemia was maintained between the intervention group and the comparator group when van Loon 2014<sup>49</sup> was excluded from the analysis, although the RR is lower than in the main analysis (RR 0.66, 95% CI 0.43 to 1.00, I<sup>2</sup> = 57%) (Table 3). A non-statistically significant difference in experiencing severe hypoxemia was also maintained between the intervention group and the comparator group when Qadeer 2009<sup>52</sup> was excluded from the analysis, although the RR is higher than in the main analysis (RR 0.78, 95% CI 0.51 to 1.20, I<sup>2</sup> = 43%) (Table 3).

**Table 3: Pooled analysis for the detection of respiratory failure (severe hypoxemia) for adults undergoing procedural sedation (randomized studies only, random effects model)**

Severe hypoxemia (SpO <sub>2</sub> < 88% to SpO <sub>2</sub> < 81%)	Standard monitoring + capnography		Standard monitoring		Effect estimate and measure of heterogeneity			
	Events	Total	Events	Total	RR	95% CI	I <sup>2</sup>	
<b>Primary analysis</b> (Total number of patients = 2492)								
Randomized studies (n=5)	88	1243	127	1249	0.70	0.48	1.02	50%
<b>Sensitivity analyses</b>								
Excluding van Loon 2014 <sup>49</sup> (n=4) <sup>a</sup>	81	1037	121	1040	0.66	0.43	1.00	57%
Excluding Qadeer 2009 <sup>52</sup> (n=4) <sup>b</sup>	69	1119	89	1126	0.78	0.51	1.20	43%

CI = confidence interval; RCT = randomized controlled trial; RR = risk ratio; SpO<sub>2</sub> = arterial oxygen saturation measured with pulse oximetry

<sup>a</sup>Limited to studies with patients undergoing clinically similar procedures.

<sup>b</sup>Limited to studies that use propofol alone or propofol in combination with other drugs for sedation.

*Detection of respiratory failure: All reported SpO<sub>2</sub> measures*

### Capnography versus standard monitoring

All other study specific measures of SpO<sub>2</sub> that were not included in the pooled analysis are included in Table 56 (APPENDIX K). Three RCTs<sup>37,47,49</sup> and one prospective cohort study<sup>55</sup> reported additional measures of oxygen desaturation that did not fall within the definitions of hypoxemia and severe hypoxemia that were used for the pooled analysis. Among the randomized studies, there were no statistically significant differences in the remaining SpO<sub>2</sub> outcomes between groups, except in Beitz 2012<sup>37</sup> where a statically significantly greater number of oxygen desaturation events detected in the comparator group compared to the intervention group ( $P < 0.001$ ). Among the prospective cohort studies, one study reported outcomes measured by pulse oximetry.<sup>55</sup> In Schlag 2013,<sup>55</sup> hypoxemia was detected in three patients, of which, all three were predicted by capnography and one of the three was predicted clinically ( $P = 0.22$ ). Likewise, a greater number of oxygen desaturation events were predicted by capnography compared to clinical observation (n = 10, 80% versus 20% respectively).

Overall, there was a lower likelihood of hypoxemia when patients were monitored with capnography. These results were statistically significant for hypoxemia, numerically lower for severe hypoxemia, and were most often lower for other measures of SpO<sub>2</sub>. One observational study reported greater ability to predict the occurrence of hypoxemia with the use of capnography.

#### 4.2.5.1.2 Other clinical effectiveness outcomes

*Detection of a respiratory event*

### Capnography versus standard monitoring

Among the randomized studies, four studies reported an outcome related to a respiratory event (Table 57).<sup>18,19,37,52</sup> The definition of a respiratory event was inconsistent between studies. In three studies,<sup>18,19,37</sup> a respiratory event (as indicated by apnea, altered ventilation, and respiratory depression), was defined by ETCO<sub>2</sub> and waveform criteria. There was no comparative evidence available in one study.<sup>19</sup> In Beitz 2012,<sup>37</sup> there was a statistically significantly greater proportion of patients who experienced apnea or altered ventilation in the intervention group versus the comparator group (56.7% versus 2.1% respectively,  $P < 0.001$ ). In

Deitch 2010,<sup>18</sup> there were approximately an equal number of events in the intervention and comparator groups (57% versus 58% respectively). In the fourth study, Qadeer 2009,<sup>52</sup> the definition of abnormal ventilation was the same as the criteria that were used to signal to the treatment team that the patient was not breathing properly (i.e., a flat waveform for > 5 seconds, a > 75% reduction in waveform amplitude compared to baseline, or a respiratory rate of < 8 breaths/min). There were no statistically significant differences between the intervention and comparator groups for the number of patients experiencing abnormal ventilation (77% versus 82%,  $P = 0.29$ ). Apnea was a more progressed version of abnormal ventilation (defined by a flat capnographic waveform  $\geq 15$  seconds). There were statistically significantly fewer proportion of patients experiencing an apnea event in the intervention group versus the comparator group (63% versus 41%,  $P < 0.001$ ).<sup>52</sup>

Among the prospective cohort studies, four studies reported an outcome related to a respiratory event (Table 57).<sup>48,53-55</sup> There was no comparative evidence available in Cacho 2010.<sup>57</sup> In Schlag 2013,<sup>55</sup> 20 patients experienced apnea, of which, there were a statistically significantly greater proportion of patients detected as having apnea with capnography data compared to those detected by clinical observation (80% versus 30% respectively,  $P = 0.001$ ). Likewise, in Deitch 2008,<sup>53</sup> the proportion of patients with recognized respiratory depression by capnography data was numerically greater in the intervention group compared to the comparator group, but only for those patients in the supplemental oxygen group (77% versus 37%), and not the room air group (59% versus 59%); no statistical testing was conducted. In Deitch 2007,<sup>54</sup> the proportion of patients with recognized respiratory depression by capnography data was greater in the intervention group compared to the comparator group, for those patients in the supplemental oxygen group (95% versus 15%), and in the room air group (84% versus 26%); no statistical testing was conducted. Burton 2006,<sup>48</sup> reported 20 acute respiratory events detected by pulse oximetry and clinical observation from 60 encounters with 59 patients. Of these 20 acute respiratory events, 17 were detected by capnography data, and 14 of the 17 events were detected by ET $\text{CO}_2$  data prior to standard monitoring.

Where comparative evidence was available, the ability to detect a respiratory event was generally favoured with the use of capnography compared to standard monitoring. Evidence from two studies suggests that capnography may be of particular benefit for monitoring patients who are receiving supplemental oxygen.

### **Capnography versus standard monitoring and rainbow acoustic monitoring**

One study compared the effectiveness of capnography versus RAM and clinical observation for detecting a respiratory pause (Table 58).<sup>50</sup> A greater proportion of patients were identified as having a respiratory pause based on capnography data compared to RAM data and clinical observation (88% versus 55% versus 16% respectively); no statistical testing was conducted.<sup>50</sup>

### **Capnography versus transcutaneous capnography**

Two studies compared the effectiveness of capnography versus transcutaneous capnography for detecting hypoventilation (Table 59).<sup>51,56</sup> In De Oliveira 2010,<sup>51</sup> a smaller proportion of patients were identified as having hypoventilation based on capnography data compared to transcutaneous capnography data (1/12, 8.3% versus 12/12, 100%); this result was not statistically significant ( $P = 0.09$ ).<sup>51</sup> In Kusunoki 2012,<sup>56</sup> there were 12 events of  $\text{SpO}_2 < 90\%$ , for which ET $\text{CO}_2$  capnography detected a decrease in respiratory rate prior to the event in 10 (83%) of these events; transcutaneous capnography did not provide any indication of the observed events prior to their occurrence.

### Time to detection of a respiratory event

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the time to detection of a respiratory event.

### Change in clinical management

#### Capnography versus standard monitoring

There were one or more outcomes reported for change in clinical management in all six randomized studies,<sup>18,19,37,47,49,52</sup> and three of the prospective cohort studies.<sup>48,54,57</sup> Pooled analysis was possible for the five randomized studies that reported the number of patients that required changes to supplemental oxygen,<sup>19,37,47,49,52</sup> and the three randomized studies that reported the number of patients that required ventilation support.<sup>19,37,47</sup> There were no statistically significant differences between the intervention group (capnography with standard monitoring) versus the comparator group (standard monitoring) for the need for supplemental oxygen (RR 0.93, 95% CI 0.73 to 1.20) (Table 4). There was evidence for moderate or substantial heterogeneity between studies ( $\text{Chi}^2 = 8.92$ ,  $\text{df} = 4$ ,  $P=0.06$ ;  $I^2 = 55\%$ ).<sup>75</sup> Differences in study design, the threshold for clinical intervention between centres and physicians, and patient characteristics (procedures performed, depth of sedation, and duration of procedure) were actively explored as possible sources of heterogeneity for this analysis. Individual study data and a forest plot can be found in Table 60 and Figure 8 respectively of APPENDIX K.

**Table 4: Pooled analysis for change in clinical management (supplemental oxygen) for adults undergoing procedural sedation (randomized studies, random effects model)**

Change in clinical management (supplemental oxygen)	Standard monitoring + capnography		Standard monitoring		Effect estimate and measure of heterogeneity			
	Events	Total	Events	Total	RR	95% CI	$I^2$	
<b>Primary analysis</b> (Total number of patients = 3002)								
Randomized studies (n=5)	189	1502	200	1500	0.93	0.73	1.20	55%

CI = confidence interval; RCT = randomized controlled trial; RR = risk ratio

The need for ventilation support was reported in three randomized studies. Pooled analysis showed that the need for ventilation support was rare, and that there were no statistically significant differences between the intervention group (capnography with standard monitoring) versus the comparator group (standard monitoring) for the need for ventilation support (RR 0.58, 95% CI 0.26 to 1.28) (Table 5). There was no evidence of heterogeneity between studies ( $\text{Chi}^2 = 0.17$ ,  $\text{df} = 2$ ,  $P=0.92$ ;  $I^2 = 0\%$ ).<sup>75</sup> Individual study data and the forest plot can be found in Table 60 and Figure 9 respectively of APPENDIX K.

**Table 5: Pooled analysis for change in clinical management (ventilation support) for adults undergoing procedural sedation (randomized studies only, random effects model)**

Change in clinical management (ventilation support)	Standard monitoring + capnography		Standard monitoring		Effect estimate and measure of heterogeneity			
	Events	Total	Events	Total	RR	95% CI	$I^2$	
<b>Primary analysis</b>								
Randomized studies (n=3)	9	913	16	917	0.58	0.26	1.28	0%

CI = confidence interval; RCT = randomized controlled trial; RR = risk ratio

Other changes in clinical management to restore proper ventilation that were unable to be pooled due to variations in the definition of the outcome are reported in Table 61. Chin lift or jaw thrust was a commonly performed intervention reported by van Loon 2014,<sup>49</sup> with a statistically significantly greater number of patients experiencing the maneuver in the intervention group versus the comparator group (49.5% versus 32.1%,  $P < 0.001$ ). Likewise, a greater number of changes in patient management was performed in the intervention arm versus the comparator arm for patients in three studies<sup>18,47,49</sup> who underwent premature termination of sedation,<sup>49</sup> who required the use of a tongue/nasal airway holder,<sup>47</sup> or who received a physician intervention (which included verbal and physical stimulation, airway realignment, supplemental oxygen, use of airway adjuncts, assisted ventilation, or intubation).<sup>18</sup> The number of patients requiring suction in Slagelse 2013<sup>47</sup> was generally similar between the intervention and comparator groups (8% versus 8.3%,  $P = 0.89$ ), and there were no patients in either the control or intervention groups in Slagelse 2013<sup>47</sup> and Qadeer 2009,<sup>52</sup> for which the procedure had to be discontinued or for which patients required the use of reversal agents, respectively. In the prospective cohort studies, the changes in clinical management were only recorded for patients who were detected as having a respiratory event; no comparative trends were evident.

Among the most commonly reported changes in clinical management during procedural sedation, oxygen supplementation and ventilation assistance, there was no evidence for statistically significant differences in the frequency of occurrence between patients receiving capnography and patients receiving standard monitoring. Major changes to clinical management such as the termination of the procedure or the use of reversal agents were rare and minor changes in clinical management such as chin-lift, jaw thrust, generally occurred more frequently for patients being monitored with capnography compared to patients receiving standard monitoring.

*Survival to hospital discharge, Discharge with full neurological functioning, Hypoxia and Organ damage*

### **Capnography versus standard monitoring**

Three randomized studies<sup>19,37,52</sup> and one prospective cohort study<sup>55</sup> reported the rate of death or permanent disability in a study-defined outcome measure: serious adverse events. There were no reported deaths or cases of permanent disability in either the intervention or the control group among the four studies that reported this outcome (Table 62).

*Length of stay in hospital*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for length of stay in hospital.

*Correct placement of an endotracheal tube*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the correct placement of an endotracheal tube.

### **Harms**

*Displacement of a ventilation/intubation tube*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for displacement of a ventilation/intubation tube.

#### *Adverse events related to the capnography device*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for adverse events related to the capnography device.

### **4.2.5.2 Research Question 2: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing procedural sedation**

#### **4.2.5.2.1 Primary clinical effectiveness outcome**

*Detection of respiratory failure: All reported SpO<sub>2</sub> measures*

#### **Capnography versus standard monitoring**

Two randomized studies reported outcomes based on pulse oximetry for pediatric patients undergoing procedural sedation (Table 63). Langhan 2015<sup>63</sup> defined oxygen desaturation as SpO<sub>2</sub> < 95% and Lightdale 2006<sup>60</sup> as a SpO<sub>2</sub> < 95% for > 5 seconds. The proportion of patients experiencing oxygen desaturation in Langhan 2015<sup>63</sup> was equivalent between the intervention and comparator groups (30% and 30% respectively) while a statistically significantly smaller proportion of patients in the intervention arm versus the comparator arm experienced oxygen desaturation in Lightdale 2006 (10.8% versus 25%,  $P = 0.024$ ).<sup>60</sup>

#### **4.2.5.2.2 Other clinical effectiveness outcomes**

*Detection of a respiratory event*

#### **Capnography versus standard monitoring**

Three of four studies reported an outcome for the incidence of respiratory events during the study (Table 64).<sup>61-63</sup> No comparative evidence was available for the proportion of patients experiencing ETCO<sub>2</sub> abnormalities in Kannikeswaran 2011.<sup>62</sup> There were no statistically significant differences in the proportion of patients with detected hypoventilation in the intervention group versus the comparator group in Langhan 2015 (44% versus 47% respectively,  $P = 0.87$ ).<sup>63</sup> Anderson 2007<sup>61</sup> reported fewer adverse airway and respiratory events detected by capnography compared to events detected by standard monitoring (79% versus 100% respectively); no statistical testing was conducted.

*Time to detection of a respiratory event*

No studies assessed the effectiveness of capnography compared to other forms of non-invasive ventilation monitoring for time to detection of a respiratory event for pediatric patients undergoing procedural sedation.

*Change in clinical management*

#### **Capnography versus standard monitoring**

Three studies reported an outcome related to a change in clinical management of pediatric patients undergoing procedural sedation (Table 65).<sup>60,61,63</sup> There were no statistically significant differences in the proportion of patients who received an intervention to restore normal ventilation in Langan 2015,<sup>63</sup> except for head tilt or jaw thrust, for which a statistically significantly lower percentage of patients received the intervention in the intervention group versus the comparator group (3.9% versus 14.3%,  $P = 0.02$ ).<sup>63</sup> In Lightdale 2006, no patients in the intervention and comparator groups received bag-mask ventilation, sedation reversal agents or premature termination of the procedure.<sup>60</sup> In the prospective cohort study,<sup>61</sup> the changes in clinical management were only recorded for patients who were detected as having a respiratory event and no comparative trends were evident.

No studies assessed the effectiveness of capnography compared to other forms of monitoring for other pre-specified clinical effectiveness outcomes for pediatric patients undergoing procedural sedation including: survival to hospital discharge, discharge with full neurological functioning, hypoxia, organ damage, length of stay in hospital, or correct placement of an endotracheal tube.

## **Harms**

### *Displacement of a ventilation or intubation tube*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for displacement of a ventilation or intubation tube for pediatric patients undergoing procedural sedation.

### *Adverse events related to the capnography device*

One study reported outcomes related to adverse events due to capnography (Table 66). Lightdale 2006<sup>60</sup> reported no adverse events related to the capnography device or participation in the study.

## **4.2.5.3 Research Question 3: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients undergoing CPR**

### **4.2.5.3.1 Primary clinical effectiveness outcome**

#### *Survival of acute event*

#### **Capnography versus no capnography**

One study reported the rate of survival of the CPR event (Table 67).<sup>65</sup> The proportion of patients reported to have survived the acute event was approximately double in the group that had documented use of ETCO<sub>2</sub> compared to the group that had no record of ETCO<sub>2</sub> use (28.3% versus 14.2% respectively), although no formal statistical testing was reported, or conducted.

### **4.2.5.3.2 Other clinical effectiveness outcomes**

#### *Return of spontaneous circulation*

#### **Capnography versus no capnography**

One study reported the number of patients who were documented as having had a sustained return of spontaneous circulation following CPR (Table 68).<sup>65</sup> The proportion of patients reported to have a sustained return of spontaneous circulation was approximately double in the group that had a documented use of ETCO<sub>2</sub> compared to the group that had no record of ETCO<sub>2</sub> use (28.3% versus 14.2% respectively; OR 2.39; 95% CI 1.29 to 4.46).

#### *Effectiveness of chest compressions*

No studies assessed the effectiveness of capnography compared to other forms of non-invasive respiration and ventilation monitoring for monitoring the effectiveness of chest compressions for adult patients undergoing CPR.

#### *Detection of respiratory failure*

No studies assessed the effectiveness of capnography compared to other forms of non-invasive respiration and ventilation monitoring for the detection of respiratory failure for adult patients undergoing CPR.

#### *Detection of a respiratory event*

### **Capnography versus chest wall impedance**

Edelson 2010<sup>64</sup> reported hyperventilation as an outcome measure related to the detection of a respiratory event. It was defined as > 10 ventilations per minute (Table 69). There were no statistically significant differences in the number of hyperventilation events detected by capnography versus chest wall impedance (86% versus 81%, respectively,  $P = 0.44$ ).

#### *Change in clinical management*

No studies assessed the effectiveness of capnography compared to other forms of non-invasive respiration and ventilation monitoring for changes in clinical management for adult patients undergoing CPR.

#### *Survival to hospital discharge*

### **Capnography versus no capnography**

One study reported the number of patients who survived to hospital discharge following an out of hospital CPR event (Table 70).<sup>65</sup> There were no statistically significant differences in the number of patients having a record of survival to hospital discharge the intervention (documented use of ETCO<sub>2</sub>) and comparator group (no documented use of ETCO<sub>2</sub>) (1.9% versus 2.1% respectively;  $P = 0.924$ ).

No studies assessed the effectiveness of capnography compared to other forms of non-invasive ventilation monitoring for all remaining pre-specified clinical effectiveness outcomes: discharge with full neurological functioning, hypoxia, length of stay in hospital, or correct placement of an ETT for adult patients undergoing CPR.

### **Harms**

#### *Displacement of ventilation/intubation tube*

No studies assessed the effectiveness of capnography compared to other forms of non-invasive ventilation monitoring for the displacement of ventilation/intubated tube for adult patients undergoing CPR.

*Adverse events related to the capnography device*

### **Capnography versus chest wall impedance**

One outcome related to possible adverse events related to the capnography device was reported in Edelson 2010 (Table 71).<sup>64</sup> The percentage of time that the data was uninterpretable was lower for capnography compared to chest wall impedance (9.7% versus 19.5%); no statistical testing was conducted.

#### **4.2.5.4 Research Question 4: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing CPR**

No studies met the inclusion criteria of the clinical review for pediatric patients undergoing CPR.

#### **4.2.5.5 Research Question 5: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients in serious or critical condition**

##### **4.2.5.5.1 Primary clinical effectiveness outcome**

*Detection of respiratory failure*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the detection of respiratory failure for adult patients in serious or critical condition.

##### **4.2.5.5.2 Other clinical effectiveness outcomes**

No studies assessed the effectiveness of capnography compared to other forms of monitoring for other pre-specified clinical effectiveness outcomes for adult patients in serious or critical condition including: detection of a respiratory event, time to detection of a respiratory event, change in clinical management, discharge with full neurological functioning, hypoxia, organ damage, or length of stay in hospital.

*Survival to hospital discharge*

### **Capnography versus standard monitoring**

The odds of death between patients monitored with capnography compared to those patients not monitored with capnography were reported in one study.<sup>66</sup> There was no statistically significant difference in odds of death in the intervention versus the comparator group (OR <0.001, 95% CI <0.001, >100) (Table 72).

*Correct placement of an endotracheal tube*

### **Capnography versus standard monitoring**

One study assessed the odds of unrecognized misplaced intubation between patients monitored with capnography versus patients not monitored with capnography.<sup>67</sup> There were no cases of unrecognized misplaced ETT when patients were monitored with capnography; 23.3% of patients who were not monitored with capnography experienced an unrecognized misplaced ETT insertion (OR 28.6, 95% CI 4.0 to 122.0), and 15% of patients who did not receive capnography for out of hospital ETT insertion died due to unrecognized improper ETT placement (Table 73).

## Harms

No studies assessed the comparative effectiveness of capnography to other forms of monitoring for the displacement of a ventilation/intubation tube or adverse events related to the capnography device for adult patients in serious or critical condition.

### **4.2.5.6 Research Question 6: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients in serious or critical condition**

#### **4.2.5.6.1 Primary clinical effectiveness outcome**

*Detection of respiratory failure*

##### **Capnography versus standard monitoring**

Hawkes 2015<sup>70</sup> and Kong 2013<sup>68</sup> both reported an outcome related to the number of patients experiencing respiratory failure upon admission to the ICU (Table 74). Hawkes 2015<sup>70</sup> compared the percentage of patients with normocapnia between the intervention and the comparator group. There were no statistically significant differences between the groups for the percentage of patients with PCO<sub>2</sub> within the target range of 5 to 8 kPa (approximately 37.5 mmHg to 60 mmHg) between the intervention and comparator groups (56.8% versus 47.9% respectively,  $P = 0.396$ ). Kong 2013<sup>68</sup> compared the percentage of patients with PCO<sub>2</sub> abnormalities (PCO<sub>2</sub> outside the target range of 40 mmHg to 60 mmHg). There were no statistically significant differences between the intervention and comparator group (37.5% versus 33.3% respectively,  $P = 0.763$ ).

#### **4.2.5.6.2 Other clinical effectiveness outcomes**

*Detection of a respiratory event*

##### **Capnography versus standard monitoring**

Kong 2013<sup>68</sup> and Kugelman 2015<sup>69</sup> reported an outcome related to the number of patients experiencing a respiratory event (Table 75). Kong 2013<sup>68</sup> compared the percentage of patients with ETCO<sub>2</sub> abnormalities between the intervention and the comparator group on admission to the ICU. There were no statistically significant differences between the groups in the proportion of patients with ETCO<sub>2</sub> outside of the target range of 40mmHg to 60mmHg between the intervention and comparator groups (33.3% versus 52.6% respectively,  $P = 0.236$ ). When the percentage of time spent outside of an unsafe ETCO<sub>2</sub> range during ventilation was measured for neonates in the ICU in Kugelman 2015,<sup>69</sup> there were statistically significant differences between the intervention and comparator groups (Table 74). Patients in the intervention group spent, on average, 3.8% of time in an unsafe high range and 3.8% of time in an unsafe low range compared to patients in the comparator group who spent, on average, 8.8% in an unsafe

high range and 8.9% of time in an unsafe low range ( $P = 0.03$ ). In this study, the unsafe  $\text{ETCO}_2$  range was defined by hypercarbia ( $\text{ETCO}_2 > 60$  mmHg) and hypocarbia ( $\text{ETCO}_2 < 30$  mmHg).

#### *Time to detection of a respiratory event*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for time to detection of a respiratory event for pediatric patients in serious or critical condition.

#### *Change in clinical management*

### **Capnography versus standard monitoring**

Two studies<sup>68,69</sup> compared outcomes related to changes in patient management (as measured by the amount of time spent on ventilation, number of blood gas samples taken and the number of ventilator setting changes) between the intervention and comparator groups (Table 76). There were no statistically significant differences in the median number of days patients were on a ventilator between the two groups in either study (median 1 versus 1.5,  $P = 0.562$ ;<sup>68</sup> median 5 versus 6,  $P = 0.62$ ).<sup>69</sup> Other measures of patient management included time on CPAP and PPV in one study.<sup>68</sup> Patients in the intervention group had a smaller mean number of minutes of CPAP and a greater mean number of minutes of PPV versus the comparator group; no statistical testing was conducted. In the Kugelman 2015,<sup>69</sup> there were no statistically significant differences in the number of arterial blood gas samples taken per hour of monitoring (median 0.22 versus 0.23,  $P = 0.43$ ), or the number of ventilator setting changes per hour of recording (median 0.05 versus 0.04,  $P = 0.94$ ).

#### *Survival to hospital discharge*

### **Capnography versus standard monitoring**

One study (Kong 2013)<sup>68</sup> compared the percentage of infants who survived to hospital discharge between the intervention group and the comparator group (Table 77). There were no statistically significant differences in the percentage of patients who survived to discharge in the intervention versus the comparator group (87.5% versus 95.8%,  $P = 0.609$ ).

No studies assessed the effectiveness of capnography compared to other forms of monitoring for other pre-specified clinical effectiveness outcomes for pediatric patients in serious or critical condition including: discharge with full neurological functioning, hypoxia, or organ damage.

#### *Length of stay in hospital*

One study (Kugelman 2015)<sup>69</sup> compared the length of stay in hospital between patients in the intervention and comparator groups (Table 78). There were no statistically significant differences in the median number of days patients spent in hospital between the intervention group and the comparator group (median 51 days, range 8 to 166 versus 58 days, range 5 to 213;  $P = 0.87$ ).

### **Capnography versus standard monitoring**

#### **Harms**

No studies assessed the effectiveness of capnography compared to other forms of monitoring for pre-specified harms outcomes for pediatric patients in serious or critical condition including:

displacement of a ventilation/intubation tube and adverse events related to the capnography device.

#### **4.2.5.7 Research Question 7: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients with known obstructive sleep apnea or receiving high-doses of opioids in post-operative care**

##### **4.2.5.7.1 Primary clinical effectiveness outcome**

###### *Detection of respiratory failure*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the detection of respiratory failure for adult patients in post-operative care settings.

##### **4.2.5.7.2 Other clinical effectiveness outcomes**

###### *Detection of a respiratory event*

Two studies compared the percentage of patients experiencing a respiratory event as detected by capnography versus the comparator.

##### **Capnography versus standard monitoring**

Hutchison 2008<sup>31</sup> compared the effectiveness of capnography to standard monitoring as defined by pulse oximetry and respiratory rate measured every four hours, for the detection of respiratory events (Table 79). There were a higher percentage of patients in which respiratory depression was detected in the capnography group versus the comparator group (52% versus 8%); no statistical testing was conducted. The number of pauses in breathing while sleeping was lower in the capnography group versus the comparator group (24% versus 48%); no statistical testing was conducted.

##### **Capnography versus rainbow acoustic monitoring**

In the prospective cohort study,<sup>71</sup> the proportion of respiratory pauses detected by capnography was statistically significantly fewer than the number of events detected by rainbow acoustic monitoring (62% versus 81%,  $P = 0.0461$ ) (Table 80).

###### *Time to detection of a respiratory event*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for time to detection of a respiratory event for adult patients in post-operative care settings.

###### *Change in clinical management*

##### **Capnography versus standard monitoring**

One study reported an outcome related to changes in patient management (Table 81). No reversal agents were used in either the intervention group or the comparator group in Hutchison 2008.<sup>31</sup>

###### *Survival to hospital discharge*

## Capnography versus standard monitoring

One study reported survival to hospital discharge (Table 82). All patients survived to hospital discharge in the intervention and comparator arm in Hutchison 2008.<sup>31</sup>

No studies assessed the effectiveness of capnography compared to other forms of monitoring for other pre-specified clinical effectiveness outcomes for discharge with full neurological functioning, hypoxia, or organ damage for adult patients receiving care in a post-operative care setting.

### *Length of stay in hospital*

## Capnography versus standard monitoring

One study reported an outcome related to the length of stay in hospital (Table 83). Patients in the capnography group had a statistically significantly longer mean duration in hospital (3.9 days versus 3.8 days,  $P = 0.03$ ) and a statistically significantly longer mean total time (2.9 hours versus 2.1 hours,  $P = 0.03$ ) in the post-anesthesia care unit.<sup>31</sup> The clinical meaningfulness of this change is unknown.

### *Correct placement of an endotracheal tube*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the correct placement of an ETT for adult patients receiving care in a post-operative care setting.

## Harms

### *Displacement of a ventilation/intubation tube*

No studies assessed the effectiveness of capnography compared to other forms of monitoring for the displacement of a ventilation/intubation tube for adult patients receiving care in a post-operative care setting.

### *Adverse events related to the capnography device*

## Capnography versus rainbow acoustic monitoring

One study reported adverse events related to the capnography device (Table 84). The percentage of time that the devices did not provide data was equivalent between capnography and rainbow acoustic monitoring (<2%); no statistical testing was conducted. The percentage of time that the capnography device was not functioning reliably was 6.1%; these data were not available for the rainbow acoustic monitoring device.<sup>71</sup>

### **4.2.5.8 Research Question 8: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care**

No studies met the inclusion criteria of the clinical review for pediatric patients in post-operative care settings.

## 5 ECONOMIC REVIEW

### 5.1 Review of Economic Studies

A review of the literature was conducted to identify existing published studies on the economic value of capnography monitoring. Only one peer-reviewed costing study was identified conducted in the United States.<sup>76</sup> This was a retrospective review of a quality improvement project that assessed and compared the utilization of blood gases before and after the implementation of standard continuous side stream capnography for all mechanically ventilated patients in the pediatric intensive care unit. The main objective of this study was to determine whether or not the implementation of capnography monitoring decreased the utilization of blood gases resulting in decreased charges in blood gases. This costing study had several limitations, including reliance on observational data, not capturing all relevant costs and not performing an incremental analysis. Its generalizability to the Canadian setting is further questionable given potential differences in clinical practice and associated health systems costs. Detailed methods and results of the economic literature search can be found in Appendix A (literature search strategy) and Appendix B.

Even though abstracts were excluded from this review, two were identified on the use of capnography in sedation patients. Both abstracts investigated capnography monitoring during procedural sedation for gastrointestinal endoscopy in adults. Jopling et al.<sup>77</sup> created a gastroenterology cost-avoidance model to determine the net economic impact of capnography monitoring during procedural sedation for a typical hospital-based gastroenterology suite. The median annual cost avoidance with routine capnography monitoring was calculated as \$304,234 compared to standard monitoring. Saunders et al.<sup>78</sup> was the only full economic evaluation that estimated the cost-effectiveness of adding capnography for moderate sedation during gastrointestinal endoscopy. The base-case result suggested that utilization of capnography reduced the proportion of patients experiencing one or more acute events (i.e., apnea, aspiration, bradycardia, desaturation, hypotension and respiratory compromise) by 18.0% and resulted in a cost savings of \$55 per procedure in one year. The authors concluded that capnography is likely to be cost-effective for monitoring moderate sedation in the US. However, limited information was available to fully assess the applicability of the findings to our specific research questions.

Overall, there is little published economic evidence addressing the two research questions outlined in this review. Accordingly, a primary economic evaluation was developed to evaluate the cost-effectiveness of capnography monitoring compared with standard monitoring using the clinical data that was collected in this review, when possible.

### 5.2 Primary Economic Evaluation

#### 5.2.1 Methods

The objective of the economic analysis was to address the cost-effectiveness in the eight clinical populations outlined in the clinical review (Table 1). Due to the lack of clinical evidence found in the clinical review for the use of capnography in pediatric patients undergoing CPR or in post-operative care, de novo economic evaluations were not conducted for these populations. Economic analyses were conducted for the remaining six patient populations, as outlined in Table 6.

### 5.2.1.1 Type of analysis

The type of analysis conducted for each patient population is listed in Table 6. The original intent of the modelling exercise was to conduct a cost-effectiveness analysis (CEA) although this was subject to the clinical findings.

#### Primary analysis

A cost-effectiveness analysis was conducted to compare capnography plus standard monitoring to standard monitoring alone in adult patients undergoing procedural sedation and CPR. For pediatric patients receiving procedural sedation, the clinical review indicated no clear direction of the clinical benefit for capnography in terms the proportion of patients experiencing oxygen desaturation and change in clinical management. A cost-minimization analysis (CMA) was therefore conducted to assess the cost difference between capnography and standard monitoring to standard monitoring alone.

For neonates in serious or critical condition, there was no clinical evidence for outcomes related to changes in clinical management in response to capnography data such as increased oxygen supplementation or chin-lift and jaw thrust. The clinical evidence also suggested no statistically significant differences in continuous capnography monitoring in detecting respiratory events and respiratory failure. Therefore, the focus of the analysis for this population was a cost consequence analysis (CCA) with the number of endotracheal tube (ETT) misplacements detected considered the measure of 'consequence' of interest.

#### Exploratory analysis

Although the clinical review provided some evidence on the comparative treatment effect of capnography for adult patients in serious or critical condition and adult patients receiving post-operative care, no comparative literature was found for two key outcomes required in the model: detection of respiratory failure and detection of a respiratory event. An exploratory analysis was therefore conducted to assess the cost-effectiveness of capnography in these populations using data generalized from adults receiving procedural sedation. This data included the risk ratio of detecting a respiratory event in patients monitored with capnography and standard monitoring compared to standard monitoring alone.

### 5.2.1.2 Target populations and settings

The target patient populations of interest were aligned to the clinical review, and are outlined in Table 6. With the exception of CPR where the base-case analysis was based on clinical data of patients receiving capnography for out-of-hospital cardiac arrest and who were then subsequently hospitalized, capnography monitoring was used solely in the hospital setting for the remaining patient population. A secondary analysis was conducted in the CPR population in which the clinical parameters were based on a study of patients who were all in a hospital setting at the onset of their cardiac arrest.

Population	Intervention	Comparator	Analysis Type
Adult patients undergoing procedural sedation	Capnography + SM	SM	CEA, PRM
Pediatric patients undergoing procedural sedation	Capnography + SM	SM	CMA, PRM
Adult patients undergoing CPR	Capnography + SM	SM	CEA, PRM
Neonatal patients in SCC	Capnography +	Clinical observation	CCA, PRM

	clinical observation		
Adult patients in SCC	Capnography	No capnography	CEA, EXP
Adult patients in post-operative care	Capnography + SM	SM	CEA, EXP

CEA = cost-effectiveness analysis; CMA = cost-minimization analysis; CPR = cardiopulmonary resuscitation; EXP = exploratory analysis; PRM = primary analysis; SCC = serious or critical condition; SM = standard monitoring

### 5.2.1.3 Interventions

As listed in Table 6, the intervention of interest in the economic analysis was most commonly capnography plus standard monitoring. For adults in serious or critical condition, the intervention was capnography alone. Standard monitoring differed by clinical area and the definition used in the economic analysis was based on the findings from the clinical review. Standard monitoring may have included: pulse oximetry plus clinical observation for adult and pediatric patients undergoing procedural sedation and adult patients in post-operative care; auscultation for adult patients undergoing CPR; and clinical observation for neonatal patients in serious or critical condition. For adult patients in serious or critical condition, the comparator was no capnography (Table 6).

### 5.2.1.4 Perspective

This analysis was conducted from the perspective of a third-party payer (i.e., public health care payer) and considered direct medical service costs associated with ETCO<sub>2</sub> monitoring including costs of capnography, as well as physician and hospital costs for respiratory failure, neurological impairment, and in-hospital death due to respiratory failure.

### 5.2.1.5 Decision analytic model

As each patient population has a unique clinical treatment pathway, decision analytic models were developed, specific to each patient population, to assess the effectiveness and associated cost implications of capnography compared with standard monitoring.

Figure 1 shows the decision analytic model for adult and pediatric patients undergoing procedural sedation and for adult patients in post-operative care. The primary benefit of capnography is the ability to detect and manage respiratory events (defined as hypoventilation or respiratory depression in sedation and post-operative patients, respectively) earlier than standard monitoring, with the aim of preventing respiratory failure, and further complications such as organ damage or death. The model therefore considered the risk of developing a respiratory event, respiratory failure, and organ damage. All patients in the model were assumed not to be intubated. Those patients who do not experience a respiratory event received routine treatment, and were then considered to be alive and discharged. Monitoring patients with capnography permits the identification of patients experiencing a respiratory event and results in changes in patient management (e.g., jaw thrusts, chin-lifts) to prevent the progression to respiratory failure. In a proportion of these patients, respiratory failure is averted and these patients are assumed to remain alive and discharged whereas, in another proportion, respiratory failure may subsequently develop. Those experiencing respiratory failure were then considered either to be alive and discharged with or without organ damage, or to have died in hospital.

**Figure 1: Model for adult and pediatric patients undergoing procedural sedation and for adult patients in post-operative care**

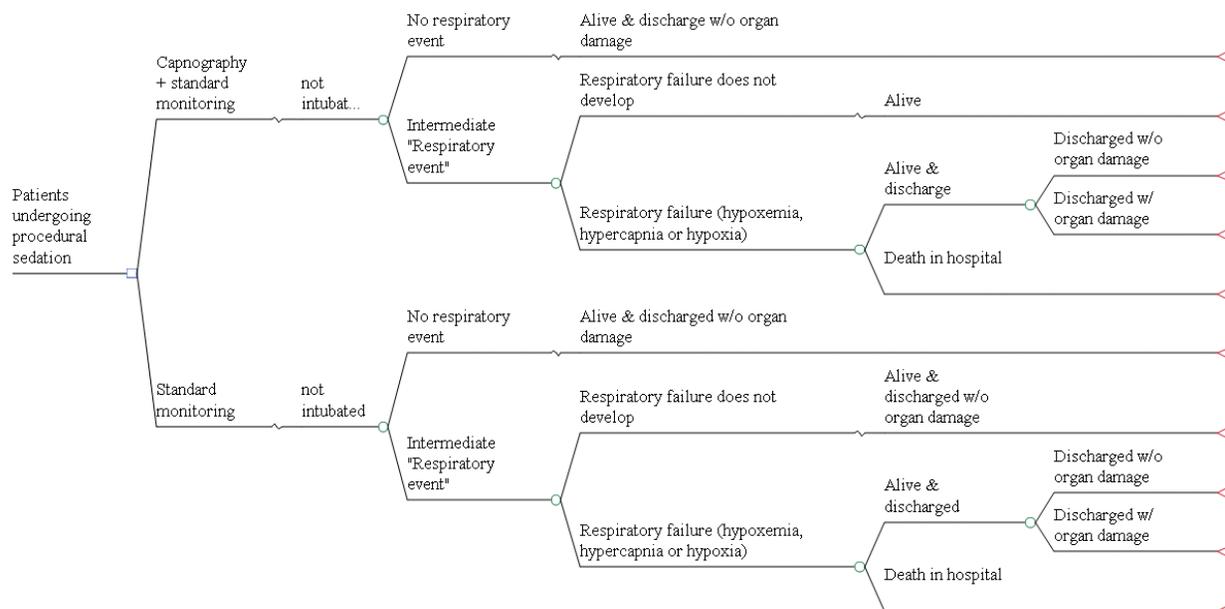

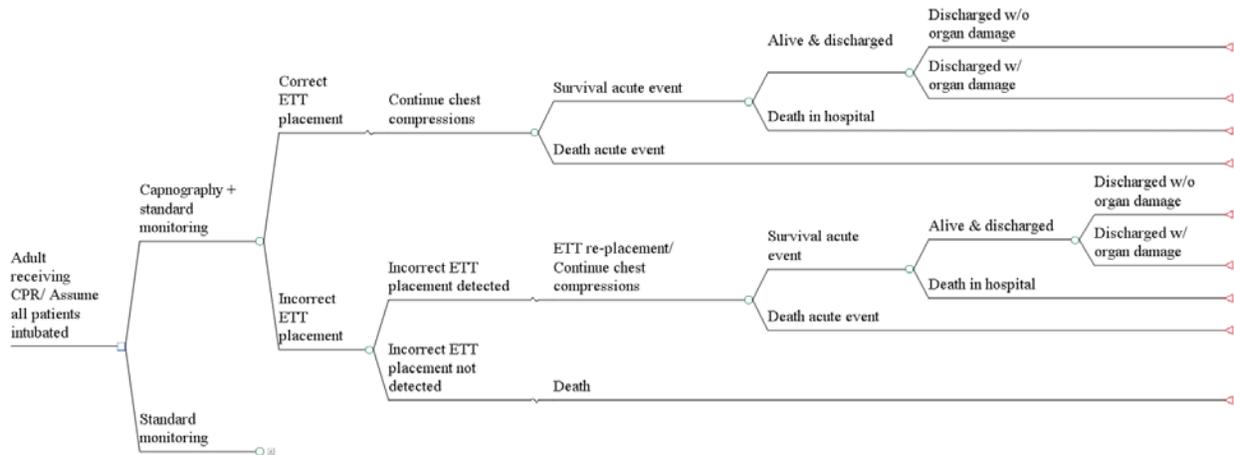

Figure 2 shows the model for adult patients undergoing CPR. This model was designed to reflect the clinical benefit of capnography with regards to the detection of an incorrect ETT placement, the likelihood of return of spontaneous circulation, and the risk of organ damage. To reflect clinical practice, the model considers all patients as being intubated. The ETT can be placed either correctly or incorrectly. For patients with incorrect ETT placement, the misplaced ETT can either be detected or undetected by the monitoring modality. If misplacement of the ETT is detected, the ETT will be adjusted and, in patients with correct and corrected ETT placements, they may survive or die from the acute cardiac event. In patients who survive the acute event, a proportion will survive to hospital discharge, with or without organ damage arising due to delays in return to circulation. There is no chance of survival if a misplaced ETT is not detected.

The model for adult patients in serious or critical condition considered the impact of monitoring on the detection of an incorrect ETT placement, the risk of developing respiratory failure, and the risk of organ damage. Representation of the model structure for this population is shown in Figure 3. All patients began the model with ETT intubation that may either be correctly or incorrectly placed. For patients with an incorrect ETT placement, the different monitoring modalities will be able to, at different rates, detect the misplacement. If misplacement is detected, the placement of the tube will be corrected. In patients with correct and corrected ETT placement, some may develop respiratory failure and subsequently organ damage. Capnography monitoring is intended to lead to earlier detection of respiratory events, prompting changes in patient management (e.g. jaw thrusts, chin-lifts), and reducing the risk of developing respiratory failure. Patients with undetected misplacement may either die in hospital, or be alive and discharged with or without organ damage.

**Figure 2: Model for intubated adult patients undergoing CPR (the decision pathway is identical in both arms of the model)**

**Figure 3: Model for intubated adult patients in serious or critical condition (the decision pathway is identical in both arms of the model)**

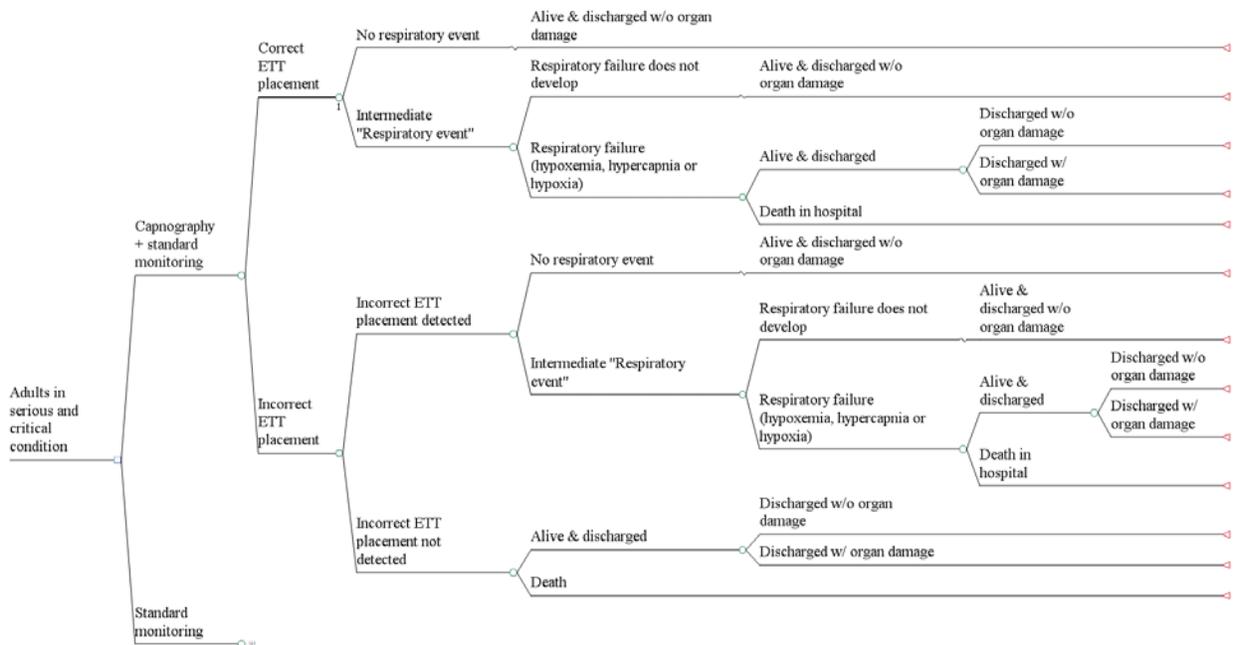

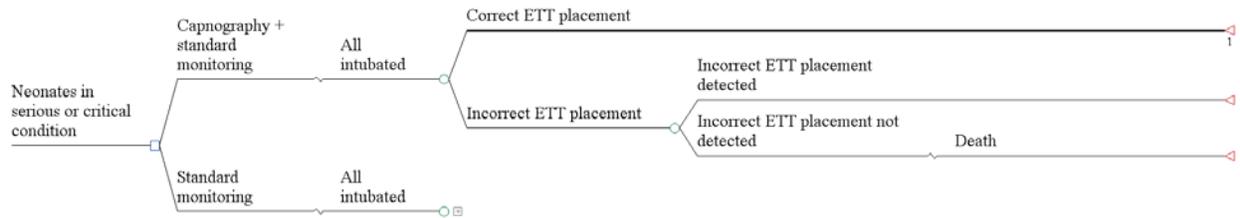

Figure 4 shows the model for neonates in serious or critical condition that require intubation. As the main outcome of interest was detection of ETT placement, a proportion of patients will have incorrect ETT placement. The model assesses the impact of capnography on the detection rate of misplaced ETT. Undetected misplaced ETT was assumed to be fatal.

**Figure 4: Model for intubated neonate patients in serious or critical condition (the decision pathway is identical in both arms of the model)**

All analyses were conducted using TreeAge Pro Suite (TreeAge Software Inc.; Williamstown, MA).

### 5.2.1.6 Clinical model inputs

The clinical model inputs required for each target population are shown in Table 85, Table 86 and Table 87 of Appendix L. When possible, this data were derived from the pooled analysis of the findings in the clinical review (Table 2, Table 4, and Table 5). The published literature was used to collect data that were unavailable from the clinical review. As some of the respiratory parameters for adult patients in serious or critical care and for adult patients in post-operative care were unavailable from the present literature, these data were generalized from the clinical findings for patients undergoing procedural sedation (Appendix L - Table 86).

For the adult CPR population, two studies were identified that provided data on the probabilities for return of spontaneous circulation and survival to hospital discharge. The first study, identified as part of the clinical review, was an observational study conducted in Taiwan by Chen et al.<sup>65</sup> Given concerns with the generalizability of this study, a secondary analysis was conducted using parameters from Phelan et al.<sup>79</sup> Phelan et al.<sup>79</sup> reported considerably higher probabilities of survival (i.e., probability of survival of acute event: capnography: 53.6% versus auscultation: 48.7%; probability of survival to hospital discharge: capnography: 35.19 % versus auscultation: 33.82%) compared to the probabilities reported in Chen et al.<sup>65</sup> (i.e., probability of survival of acute event: documented use of ETCO<sub>2</sub>: 28.3% versus no documented use of ETCO<sub>2</sub>: 14.2%; probability of survival to hospital discharge: documented use of ETCO<sub>2</sub>: 1.9 % versus no documented use of ETCO<sub>2</sub>: 2.1%). Although the study by Phelan et al.<sup>79</sup> was conducted in the US and Canada, it was considered a secondary analysis given that the number of ETT placements confirmed by capnography and an esophageal detector device were reported as a combined group. It is unclear what proportion of ETT placements were detected by capnography and what proportion were confirmed by the esophageal detector device to allow for an independent assessment of the comparative effectiveness of capnography for confirming ETT placement compared to auscultation.

### 5.2.1.7 Cost inputs

Cost data included physician and hospital services that are associated with treatment for respiratory failure, neurological impairment, and in-hospital death due to respiratory failure (Appendix L - Table 88). The cost data were primarily obtained from Ontario sources, with physician costs obtained from the schedule of benefits for physician services while hospital costs for respiratory failure and in-hospital death taken from the Ontario Case Costing Initiative. The cost of treatment for organ damage was obtained from an Ontario study.<sup>80</sup> If necessary, details on resource utilization were informed by the clinical experts involved in this review. For instance, it was noted that patients with endotracheal intubation would have had their supplemental oxygen maximized, regardless of monitoring method. As such, change in clinical

management (with oxygen supplementation) was not captured in the economic models where patients were assumed to be intubated at the start of the model (e.g., CPR and serious or critical condition).

The cost of ETCO<sub>2</sub> monitoring by capnography was also included. The purchase price of capnography and the cost of the associated consumable supplies were obtained from a program in British Columbia (*Richard Milo, KGH Respiratory Services, Kelowna, BC: personal communication, 2015 Nov*). Since the cost data of ETT placement and supplemental oxygen was limited, it was derived based on an unpublished manuscript.<sup>81</sup> US dollars reported in this study were converted to Canadian dollars using purchasing power parity collected from Statistics Canada. One-way sensitivity analysis was conducted by varying these costs to test their impact. All costs were converted to 2015 Canadian dollars using the Canada Consumer Price Index (CPI).

### **5.2.1.8 Model outputs**

The outputs generated from the models were as follows:

- Incremental cost per respiratory failure averted for adult patients undergoing procedural sedation and in post-operative care
- Total cost per patient for pediatric patients undergoing procedural sedation
- Number of ETT misplacements detected and the associated costs for neonatal patients in serious or critical condition
- Incremental cost per life saved for adult patients undergoing CPR and for adult patients in serious or critical condition

### **5.2.1.9 Sensitivity analysis**

Sensitivity analyses were conducted to evaluate the degree to which the uncertainty in cost and effectiveness parameters impacted the model findings. The base-case analysis findings for cost-effectiveness analysis evaluation represent the probabilistic results based on 5000 Monte Carlo simulations of the parameters' distributions listed in Table 85, Table 86, Table 87 and Table 88. The probabilistic results capture the extent to which parameter uncertainty may impact the cost-effectiveness of the model. For the CMA and CCA, the base-case analysis presents the deterministic results.

For populations in which a cost-effectiveness analysis was undertaken, one-way sensitivity analyses were performed on the lower and upper confidence interval of each model input to address its impact on the incremental cost-effectiveness ratio (ICER) and the findings are presented by a tornado diagram. When possible, the high and low parameter ranges were based on the reported 95% confidence interval. If this could not be determined or calculated, the high and low values were based on +/- 20% of the parameter's mean value. For the primary analysis, a one-way sensitivity analysis was conducted on the top five inputs that had an impact on the ICER, based on the tornado diagram.

Scenario analyses were conducted to evaluate the impact of the model to different model assumptions. In all primary full economic models (i.e., CEA and CMA), a two-way sensitivity analysis was conducted by simultaneously varying the purchase price of capnography and the number of patients the device served to assess the impact of both model parameters on the overall ICER. An additional analysis was conducted in the model for procedural sedation in adults that simultaneously varied the baseline respiratory failure rates and the relative risk of respiratory failure.

To assess structural uncertainty in the assumption that supplemental oxygen and ventilation assistance are independent in the adult procedural sedation model, an additional one-way sensitivity analysis was conducted on the proportion of patients receiving supplemental oxygen out of the patients receiving ventilation assistance.

For the exploratory analysis (i.e., adult patients in serious or critical condition or adult patients receiving post-operative care), the treatment effects of monitoring were assumed to be consistent with adult patients who underwent procedural sedation. To assess the impact of this assumption on the cost-effectiveness results, a one-way sensitivity analysis was conducted using a wider range of uncertainty as treatment effect values compared to the range of uncertainty that was used in the procedural sedation model.

#### **5.2.1.10 Time horizon and discount**

The time horizon for the economic analysis was from the start of ETCO<sub>2</sub> monitoring until hospital discharge. Given that the time horizon was less than one year, cost and health outcomes were not discounted.

#### **5.2.1.11 Model assumptions**

The economic analyses were conducted based on assumptions listed in Table 7.

<b>Assumption</b>	<b>Population</b>
Costs that apply to both arms of the model were excluded.	All populations
The life time of the capnography device was assumed to be five years, and purchase cost was therefore amortized over that time period.	All populations
Patients were assumed to receive independently ventilation assistance and supplemental oxygen for the treatment of respiratory failure, and cost of both were included in the analysis.	Adults undergoing procedural sedation, or in post-operative care, or in serious or critical care
Patients were assumed not intubated at the start of the model.	Adult and pediatric patients undergoing sedation and adults in post-operative care
All patients were assumed to be intubated at the start of the model.	Adults undergoing CPR or adults and neonates in serious or critical care
The relative treatment effects of monitoring with respect to the prevention of a respiratory event in adult patients in serious or critical condition or in post-operative care were assumed to be consistent with the treatment effects observed in adults undergoing procedural sedation.	Adult patients in serious or critical condition or in post-operative care
The treatment effect with respect to the prevention of a respiratory event was assumed to be the same between capnography and standard monitoring.	Pediatric patients undergoing procedural sedation
All patients were assumed to survive to hospital discharge following respiratory failure, and none discharged with organ damage.	Pediatric patients undergoing procedural sedation
The survival rate was assumed to be zero if ETT misplacement was not detected.	Adults undergoing CPR; Neonates in serious or critical condition

CPR = cardiac pulmonary resuscitation; ETT = endotracheal tube

### **5.2.2 Results**

#### **5.2.2.1 Base-case results**

### 5.2.2.1.1 Research Question 9: Cost-effectiveness of ETCO<sub>2</sub> monitoring for adult patients

#### Primary analysis

Table 8 presents the probabilistic cost-effectiveness results of capnography plus standard monitoring compared with standard monitoring alone in the adult population. The total expected cost per patient ranged from \$62 to \$1,019 for capnography plus standard monitoring and \$29 to \$954 for standard monitoring alone. In adults receiving procedural sedation and were experiencing out-of-hospital cardiac arrest, capnography was more costly than standard monitoring with an incremental cost of \$32 and \$65, respectively. Capnography monitoring was more effective in both cases with lower respiratory failure rates (0.183 versus 0.268) in adults undergoing procedural sedation and higher survival rates (0.003 versus 0.005) in adults receiving CPR. The additional cost per respiratory failure averted was \$377 for adults receiving procedural sedation, and the additional cost per life saved was \$27,269 for out-of-hospital cardiac arrest adult patients receiving CPR.

#### Exploratory analysis

Exploratory analysis of the adult population in serious or critical condition or in post-operative care indicated that capnography was associated with both a lower cost and improved effectiveness. Therefore, capnography was deemed to be the dominant monitoring method (Table 8).

<b>Table 8: Cost-effectiveness results for adults across the different clinical application of ETCO<sub>2</sub> monitoring</b>					
Strategy	Cost (SD)	Incremental Cost	Effectiveness (SD)	Incremental Effectiveness	ICER
<b>Primary Analysis: Procedural sedation</b>

CPR= cardiopulmonary resuscitation; ICER = incremental cost-effectiveness ratio; ref = reference; SCC = serious or critical condition; SD= standard deviation; SM = standard monitoring

<sup>a</sup>Effectiveness defined as rate of respiratory failure for other settings. Lower rate of respiratory failure indicates better effectiveness.

<sup>b</sup>Effectiveness defined as survival rate.

### 5.2.2.1.2 Research Question 10: Cost-effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients

Table 9 presents the probabilistic cost-effectiveness results of capnography plus standard monitoring compared with standard monitoring alone in pediatric patients undergoing procedural

sedation. A cost-minimization analysis was undertaken given that the findings of the clinical review found no evidence to suggest a difference between the monitoring strategies for the management of patients and the development of respiratory events. Capnography with standard monitoring compared to standard monitoring alone differed primarily by the additional costs of the capnography device (i.e., \$48).

In neonatal patients with serious and critical condition, the cost consequence analysis found that capnography was less costly than standard monitoring with a cost savings of \$173.03. The intervention was more effectiveness as there were fewer undetected ETT misplacements (0.0067 versus 0.022). Table 10 presents a detailed breakdown of the cost and outcomes from this analysis.

Strategy	Cost (SD)	Incremental Cost	Effectiveness (SD)	Incremental Effectiveness	ICER
<b>Procedural sedation - Pediatrics<sup>a</sup></b>					
SM	\$66.86 (30.34)	-ref-			
Capnography + SM	\$115.13 (30.90)	\$48.27			

ref = reference; SD = standard deviation; SM = standard monitoring

<sup>a</sup>Cost-minimization analysis was conducted and, as such, there was no effectiveness presented.

	SM	Capnography + SM	Difference (capnography plus SM – SM alone)	% change
<b>Cost</b>				
Cost of additional monitoring (i.e., capnography)	0	\$48.33	\$48.33	N/A
Cost of correcting misplacement ETT	\$38.69	\$41.16	\$2.47	6.4%
<b>Total Cost</b>	<b>\$38.69</b>	<b>\$89.49</b>	<b>\$50.8</b>	<b>131.3%</b>
<b>Consequences/Events</b>				
Proportion of patients with incorrect ETT undetected	0.022	0.0067	0.0153	70%

ETT = endotracheal tube; SM = standard monitoring

### 5.2.2.2 Sensitivity analysis

#### 5.2.2.2.1 Research Question 9: Cost-effectiveness of ETCO<sub>2</sub> monitoring for adult patients

##### Primary analysis

###### Probabilistic sensitivity analysis

Figure 10 and Figure 11 in Appendix M show the cost-effectiveness acceptability curves for the populations of adults receiving procedural sedation and adults receiving CPR. The figures were generated from the 5000 Monte Carlo simulation and show the probabilities of capnography with standard monitoring being cost-effective over a range of willingness to pay (WTP) thresholds. As WTP thresholds increased, the probability in which capnography with standard monitoring would be considered most likely cost-effective increased. For adults receiving procedural sedation, capnography with standard monitoring had over a 50% probability of being cost-effective when WTP to avert a case of respiratory failure was greater than \$400. For adults receiving CPR, capnography with standard monitoring had the highest probability of being cost effective at WTP thresholds greater than \$75,000 per life saved. However, this model was

sensitive to parameter uncertainties given that the probabilities in which capnography with standard monitoring would be the most likely cost-effective strategy rarely exceeded 55%.

### ***Tornado diagram analysis***

Figure 12 and Figure 13 in Appendix M present the tornado diagrams that show the rank to which the ICER changes over a number of inputs listed on the left of the diagrams. In both models, the cost-effectiveness results were most sensitive to the relative clinical effectiveness of capnography in preventing final clinical outcomes, the baseline risks of the clinical event being modelled, and its associated costs. Further one-way sensitivity analysis was conducted on the top five inputs that had the greatest impact on the cost-effectiveness, with the findings presented in Figure 14 to Figure 25 in Appendix M.

### ***Scenario Analysis***

Two-way sensitivity analyses were conducted to assess to what extent the model findings changed under different scenarios when two parameter inputs were varied simultaneously. Table 90 in Appendix M shows the changes to the ICER when simultaneously changing the baseline rates for respiratory failure and the relative risk for respiratory failure for capnography compared to standard monitoring in adults receiving procedural sedation. As shown in Table 90 of Appendix M, as the rate of respiratory failure rose, the ICER for capnography decreased and as the relative risk of respiratory failure for capnography versus standard monitoring approached nearer to one (i.e., no treatment difference), the ICER for capnography increased.

Table 91 of Appendix M shows the cost per patient by varying the purchase price of capnography and the number of patients the device serves per month. As the purchase price rose and the number of patients served decreased, the ICER associated with capnography monitoring would increase in both adult populations.

### ***Structural sensitivity analysis***

Both models relied on several key assumptions. For the model on procedural sedation, it was assumed that patients received independently ventilation assistance and supplemental oxygen for the treatment of respiratory failure. However, clinical opinion suggested a proportion of patients may receive both. To evaluate how the ratio of the supplemental oxygen use for treatment of respiratory failure in adults receiving procedural sedation, a sensitivity analysis was conducted in which supplemental oxygen and ventilation assistance use to manage a respiratory event was varied. Results indicated that the cost-effectiveness was robust to this assumption (Appendix M - Figure 24).

A further sensitivity analysis was conducted to evaluate the impact of varying the probability of undetected ETT misplacement in standard monitoring for adults receiving CPR. Given that the clinical studies had mentioned no undetected ETT misplaced in the standard monitoring group, the original economic analysis assumed that the probability of undetected ETT misplaced would be zero in both arms of the model. The sensitivity analyses indicated that the cost-effectiveness of capnography was not sensitive to changes in the number of false negative with standard monitoring (Appendix M - Figure 25). This is likely due to the fact that the rate of incorrect ETT placement remained low and that, unless rates of incorrect ETT placement also rose, the model findings would remain robust.

### ***Secondary Analysis of CPR Adult Model***

Table 11 presents the probabilistic cost-effectiveness results of capnography plus standard monitoring compared with standard monitoring alone for the adult CPR model using the clinical survival probabilities from Phelan et al.<sup>79</sup> Given that the survival reported by Phelan et al. were

nearly 15 folds higher than those in Chen et al.'s study, the ICER associated with capnography monitoring reduced to \$4,910 per life saved. Capnography with standard monitoring was most likely cost-effective when WTP was greater than \$5250 per life saved (Appendix M - Figure 26).

**Table 11: Cost-effectiveness results in adult receiving CPR based on the clinical data from Phelan et al.<sup>79</sup>**

Strategy	Cost (SD)	Incremental Cost	Effectiveness (SD)	Incremental Effectiveness	ICER
<b>Secondary Analysis: CPR</b>					
SM	\$1,356.41 (1,000.09)	-ref-	0.165 (0.002) <sup>†</sup>	-ref-	
Capnography + SM	\$1,472.88 (972.66)	\$116.47	0.189 (0.003) <sup>†</sup>	0.024	\$4,852.92

ref = reference; SD = standard deviation; SM = standard monitoring

### Exploratory analysis

The analysis of adults with serious and critical condition and of adults receiving post-operative care was conducted using respiratory failure parameters taken from the pooled analysis of adults receiving procedural sedation from the clinical review. The cost-effectiveness acceptability curve shows that capnography with standard monitoring would remain the most likely cost-effective monitoring strategy for patients in serious or critical condition (p >99%), regardless of the WTP threshold (Appendix M - Figure 27). For adult patients receiving post-operative care, the probability in which capnography with standard monitoring would be most cost-effective rose as the WTP with a higher than 50% probability when WTP was greater than \$2250 (Appendix M - Figure 28).

One-way sensitivity analysis was conducted on these inputs to test their impact on the cost-effectiveness results. For the model for adults in post-operative care, cost-effectiveness results were found to be most sensitive to the baseline risks of respiratory failure and death, along with its associated costs (Appendix M - Figure 30). The model for adults in serious and critical condition was robust as, in changing the model parameters across a range of plausible values, capnography with standard monitoring remained the dominant strategy over capnography alone (Appendix M - Figure 29).

#### **5.2.2.2.2 Research Question 10: Cost-effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients**

In the cost-minimization analysis, only the cost of capnography appeared to impact the model's finding. As such, no probabilistic sensitivity analysis or one-way sensitivity was conducted to address the parameter uncertainty in the model for pediatric patient undergoing procedural sedation. The cost difference between the two monitoring modalities was simply the additional cost of capnography. To characterize the potential cost difference per patient based on the cost of capnography, a scenario analysis varying the purchase price of capnography and the number of patients the device serves per month was conducted. As shown, the total cost per patient receiving capnography increased as the purchase price rose and decreased as the number of patients served increased (Appendix M - Table 92).

Although no sensitivity analysis was conducted on the cost-consequence analysis, it can be observed that the cost difference between treatment strategies depends primarily on any inputs that impact the cost of the additional monitoring (e.g., capnography device, number of patients served, overall lifetime of capnography monitor) and the cost of correcting a misplaced ETT. Similarly, in terms of the clinical outcomes of number of incorrect ETT undetected, this

consequence is dependent on both the overall baseline risk of an incorrect ETT misplacement and the performance of the capnography device compared to standard monitoring.

## 6 HEALTH SERVICES IMPACT

### Implementation Considerations

Thirty-four<sup>7,23,82-113</sup> citations containing information regarding barriers, supports, and other implementation issues related to the use of capnography in the hospital and prehospital settings were identified. The identified citations reported on implementation issues in the following clinical settings: pre-hospital,<sup>82-87</sup> the emergency department and acute care,<sup>7,23,88-105</sup> the operating room,<sup>92,106-110</sup> and the post-anesthesia care unit.<sup>111-113</sup>

#### *Pre-hospital Setting*

##### **Supports**

Educating pre-hospital staff on the use of capnography has been suggested as a support to implementation.<sup>83</sup> A supportive mnemonic that mimics the “ABCs” (airway breathing, circulation) or emergency medicine has been developed for the use of ETCO<sub>2</sub> for resuscitation: P (Position of the tube); Q (Quality of chest compressions); R (Return of spontaneous circulation/detection); S (Strategy for further treatment); T (Termination of resuscitation for maximum benefit of capnography).<sup>85</sup>

##### **Barriers**

The availability of capnography equipment in a transport vehicle can further increase the likelihood of its use.<sup>86</sup> As the set-up of the equipment can be seen as a barrier to use, a pre-assembled mask or assembled mask capnography may be feasible to use during transport and pre-hospital use.<sup>87</sup>

#### *Emergency Department and Acute Care Settings*

##### **Supports**

Based on results from surveys, interviews, guidelines, and trials, there are factors that contribute to successful implementation of capnography into regular use in the emergency department and acute care. With respect to staffing and human resources, staff champions,<sup>92</sup> having a good understanding of the principles and use of capnography,<sup>92</sup> educational initiatives and training,<sup>91</sup> familiarity with capnography literature,<sup>93</sup> and having a culture of change to aid in the implementation or use of new equipment<sup>94</sup> have been identified as potential supports to implementing capnography. With respect to the physical work environment, the ability to quickly access capnography equipment,<sup>92,95</sup> and having capnography available at all bedsides in the pediatric intensive care unit (PICU)<sup>91</sup> could contribute to the successful implementation of capnography. With respect to policies and procedures, supports to implementation include identifying capnography as the standard of care,<sup>92</sup> having a policy for its use (e.g., for all intubated patients),<sup>23,92,97</sup> having a legal mandate to use capnography after endotracheal intubation (as it is in Germany),<sup>96</sup> having capnography listed in minimum equipment guidelines (as it is in some US states),<sup>91</sup> and having guidelines that support capnography for intubated patients.<sup>98</sup> Additional supports that have been identified include the short time that elapses between attaching a capnography device and obtaining a good reading,<sup>92</sup> the simplicity of using capnography equipment,<sup>97</sup> the user’s perception of capnography being inexpensive,<sup>93</sup> and that it can help provide continuity of care if capnography is already used in the pre-hospital setting.<sup>97</sup> In a study of emergency departments in Thailand, the implementation of an evidence-based care bundle that included airway management approaches, one of which being capnography, was found to increase the use of capnography where appropriate.<sup>99</sup> Some capnography interfaces are more intuitive than others or require less training.<sup>102</sup> For example, in one study,

healthcare workers were slower in activating the Dräger Evita 4 than the Dräger V500, even after specific training.<sup>102</sup> Ensuring patient safety may require both specific training and an intuitive and ergonomic interface.

Potential additional uses for capnography in the emergency department include evaluating patients with diabetic ketoacidosis,<sup>103</sup> seizures,<sup>103</sup> pulmonary embolism,<sup>103</sup> malignant hyperthermia,<sup>103</sup> and for triage.<sup>103,104</sup> In the ICU, capnography may also be used for apnea testing in patients who are suspected to be clinically brain-dead.<sup>105</sup> It can aid in detecting spontaneous respiratory movements and the printouts from the capnography machine would be useful for medico-legal purposes.<sup>105</sup> Using capnography instead of other methods (or prior to deciding if other methods are needed) can reduce the need to transport a patient who is unstable to a radiology unit, and reduce the need for contrast injections in patients for whom it is not necessary.<sup>105</sup>

### **Barriers**

Lack of equipment,<sup>93-95</sup> lack of experience with the equipment,<sup>93</sup> perceived lack of need for capnography,<sup>93</sup> perceived lack of evidence or lack of convincing evidence for its use,<sup>92,93</sup> perceived difficulty<sup>93</sup> or lack of knowledge regarding the use and interpretation of data outputs,<sup>92,114</sup> expense,<sup>93,114</sup> the need to buy new equipment if the monitors in use do not have a capnography function,<sup>97</sup> and perceived inaccurate measurements have all been identified as barriers to regular capnography use.<sup>93,114</sup> Past negative experiences,<sup>92</sup> lack of experience<sup>94</sup> or lack of familiarity with capnography equipment,<sup>97,114</sup> as well as infrequent use<sup>92</sup> of capnography can also contribute to limited uptake. Additionally, not having mandated use can decrease the likelihood that capnography will be used in all patients for whom it is indicated.<sup>92</sup> Although not identified as a harm in the studies included in the clinical review, a potential capnography-related adverse event in ICU or in immobilized patients may be tracheostomy displacement during patient movement.<sup>100</sup> The capnography line may interfere with the tracheostomy if those moving the patient are unfamiliar with where the lines are.<sup>100</sup> Awareness of clinical situations where there is a potential for adverse events or where inaccurate measurements are more common, may facilitate a cautious interpretation of capnography readings in some settings.

### *Operating Room*

#### **Supports**

Having capnography as the standard of care<sup>92</sup> has been identified as a support by healthcare professionals who work with patients under conscious sedation.

### **Barriers**

Lack of unequivocal recommendations<sup>108</sup> and lack of mandated use<sup>92</sup> for conscious sedation have been identified as barriers. An additional barrier to its use in children may be a perception that the protocols are already so rigorous that early detection of respiratory events is not an issue for children under conscious sedation.<sup>92</sup> When side-stream devices are used during head and neck surgeries, kinking of the sampling line can occur, leading to inaccurate readings. An angled insertion of the sampling line may help mitigate that problem<sup>109</sup> and therefore increase both staff confidence in capnography and the likelihood of accurate readings. Additionally, advanced auditory displays alarms may be more helpful than visual displays alone in alerting anesthesiology staff that there is a potential problem.<sup>110</sup>

### *Post-Operative Care Unit*

#### **Supports**

Supports identified for the successful implementation of capnography in the post-operative care unit include: having established processes for training staff with respect to new devices and

procedures, comprehensive protocols for the use of the monitors, highly motivated staff, a pre-existing order entry system that could include capnography, as well as having staff with a foundational knowledge of ETCO<sub>2</sub> monitors.<sup>111</sup>

### **Barriers**

Barriers of successful implementation included a lack of clarity regarding who could prescribe the use of monitors and having an insufficient number of monitors contributed to irregular use.<sup>111</sup> In an American 489 bed level 1 trauma centre, 63 ETCO<sub>2</sub> monitors was seen as a “support” to uptake and implementation; a further 30 were purchased in order to maintain a steady supply to the post-anesthesia care unit (PACU)<sup>111</sup> In a survey of PACU nurses from 90 American institutions, those who had access to capnography equipment found it to be useful for detecting opioid-related sedation events, however 75% of those surveyed could not access capnography in the PACU.<sup>113</sup>

## **7 DISCUSSION**

### **7.1 Summary of Results**

#### *ETCO<sub>2</sub> monitoring for adult and pediatric patients undergoing procedural sedation*

The results of our primary clinical analysis suggested that adult patients undergoing procedural sedation experienced fewer episodes of hypoxemia with the use of capnography. The clinical effectiveness of capnography for preventing severe hypoxemia in this population was less clear. For pediatric patient’s undergoing procedural sedation, evidence was limited and the results of our primary clinical analysis were mixed. One study found no differences in the occurrence of oxygen desaturation,<sup>63</sup> while one study favoured the use of capnography.<sup>60</sup> Study quality concerns in the pediatric population indicate the need for cautious interpretation of these results.

For other clinical effectiveness outcomes included in our review, capnography was found to offer an increased detection of respiratory events in adults undergoing procedural sedation. It is important to note that, where a respiratory event was defined by capnography criteria only, for example, in Beitz 2012,<sup>37</sup> the greater detection of respiratory events by capnography is not a fault of standard monitoring, but simply a lack of capability to detect these events as they are defined. This caveat is necessary for the appropriate interpretation of the comparison; however it does not negate the observed benefit of capnography as an additional monitoring tool for providing information about a patient’s ventilation status. Despite a greater detection in respiratory events in the adult population, there was no evidence for statistically significant differences in the frequency of use of assisted ventilation or increases in oxygen supplementation between patients receiving capnography and patients receiving standard monitoring. Changes in clinical management such as chin-lift, jaw thrust, generally occurred more frequently for patients being monitored with capnography compared to patients receiving standard monitoring. These results support the step-wise nature of the use of clinical interventions for restoring ventilation. Minor interventions such as patient repositioning or verbal or physical stimulation are implemented first, followed by more advanced interventions such as supplemental oxygen and ventilation if a patient’s condition does not improve.<sup>115</sup>

In this review’s primary economic analysis for adult patients undergoing procedural sedation, the base-care incremental cost per respiratory failure averted for capnography with standard monitoring compared with standard monitoring alone was \$377 per respiratory failure avoided. The model was found to be robust across of range of sensitivity analyses.

In the pediatric population, there was no statistically significant evidence to suggest that capnography was different than standard monitoring in its ability to detect episodes of hypoventilation, adverse airway and respiratory events, or influence clinical management.<sup>60,61,63</sup> It is unclear why one study found a statistically significantly lower percentage of patients who received head tilt and jaw thrust in the intervention group compared to the control group.<sup>63</sup> Pediatric patients may have more rapid deterioration if hypoxemia is to occur, so detecting a problem with ventilation earlier is very important in this population.<sup>116,117</sup> Our results do not demonstrate a benefit of capnography for greater detection of respiratory events, but one study of limited quality suggests that patients monitored with capnography have a decreased occurrence of oxygen desaturation with the use of capnography. The timeliness of interventions provided,<sup>63</sup> and respiratory events detected,<sup>61,62</sup> however, suggests that although the studies are unable to detect a statistically significant difference in the occurrence of respiratory events, that the timeliness of detection offers benefits that were not well captured in the included studies. Given that there was no clear direction on the clinical benefit for capnography in terms of the proportion of patients experiencing oxygen desaturation and change in clinical management, a cost-minimization analysis was conducted.

Capnography with standard monitoring was assumed to not generate additional clinical benefit over standard monitoring alone and was associated with an additional cost of \$48 per pediatric patient undergoing procedural sedation.

#### *ETCO<sub>2</sub> monitoring for adult and pediatric patients undergoing CPR*

There was limited evidence available to assess the effectiveness of capnography for monitoring adult patients undergoing CPR. For in-hospital cardiac arrests, there was no statistically significant difference between capnography and chest wall impedance in detecting episodes of hypoventilation.<sup>64</sup> Although not specified in our protocol, the outcome related to the detection of respiratory events was extracted for this population in order to better reflect the patient clinical care pathway and to subsequently help inform the economic evaluation. For patients experiencing out-of-hospital cardiac arrests, there was evidence for a greater likelihood of ROSC and survival of the acute event for patients monitored with capnography;<sup>65</sup> however, no statistically significant differences in the proportion of patients who subsequently survived to hospital discharge were found.<sup>65</sup> These results should be interpreted with caution given the low rate of exposure to capnography monitoring (83/5041, 1.6% of patients) in the study cohort.

The results of the primary economic analysis for adult patients undergoing CPR indicated that capnography improved health outcomes but at a higher cost. The incremental cost-effectiveness ratio for the base-case analysis was \$27,269 per life saved. It is important to know, however, that the economic findings were found to be highly sensitive to the mortality rates used in the model. A secondary analysis was conducted using higher survival rates reported in a study by Phelan et al.,<sup>79</sup> whereby the incremental cost-effectiveness ratio declined to \$4,910 per life saved. Possible reasons for this discrepancy include: differences in survival rates between countries, differences in survival rates between in-hospital and out-of-hospital cardiac arrests, and differences in the study design. The base-case analysis results should be interpreted as representing the likely cost-effectiveness of capnography in patients experiencing cardiac arrest out-of-hospital that were subsequently hospitalized. As it was not possible to determine the independent clinical effect of capnography in Phelan et al.,<sup>79</sup> the economic findings (i.e., secondary analysis) that were based on this study's inputs should be interpreted with caution.

No clinical trials were identified on the use of capnography in pediatric patients undergoing CPR and, as such, the clinical effectiveness and cost-effectiveness of capnography in this patient population remains unknown.

#### *ETCO<sub>2</sub> monitoring for adult and pediatric patients in serious or critical condition*

There was limited evidence to assess the effectiveness of capnography for adult patients in serious or critical condition.<sup>66,67</sup> Evidence suggested that patients monitored with capnography were less likely to experience an unrecognized misplaced ETT compared to patients who were not monitored with capnography.<sup>67</sup> Death as a result of misplaced ETT was also therefore prevented. It should be noted, however, that there were very few patients of the cohort that were exposed to ETCO<sub>2</sub> monitoring (5.9%) and the authors made no conclusions specific to capnography monitoring.<sup>67</sup> The interpretation of the results for this population is limited due to a lack of reporting of patient characteristics and details of the intervention and comparator in both studies. Given the limited clinical evidence for adult patients in serious or critical condition, the economic evaluation was an exploratory analysis that relied on the assumption that the treatment effects of capnography compared to standard monitoring for the incidence of respiratory failure would be similar to what was observed in adult patients receiving procedural sedation. This exploratory analysis showed that capnography improved health outcomes at a lower cost, and therefore dominated standard monitoring. Sensitivity analysis conducted on the model indicated that capnography remained the dominant strategy even if the relative treatment effect between capnography versus standard monitoring was less favorable than what is reported in the procedural sedation population. These results were likely driven by the higher costs of treating respiratory failure in this patient population.

The studies that met the inclusion criteria for pediatric patients in serious or critical condition included preterm newborns, or newborns that were receiving ventilation and were at high risk of needing resuscitation. One study found a statistically significant difference in the percentage of time that patients spent in an unsafe high and an unsafe low ETCO<sub>2</sub> range. This finding deserves cautious interpretation due to methodological concerns of the study. There were otherwise no statistically significant differences in the detection of respiratory events, respiratory failures, change in clinical management, survival or length of stay in hospital in the included studies.<sup>68-70</sup> Adoption of ETCO<sub>2</sub> monitoring for pediatric patients in the ICU was initially challenged because the devices were too large.<sup>118</sup> The evolution of capnography devices has enabled more widespread use in the pediatric population,<sup>118-121</sup> including neonates, yet there is still limited evidence, with most evidence based on observational trials.<sup>118</sup> In order to reflect what was found in the clinical review, a cost-consequence analysis was conducted to assess the costs of capnography, and the rate of detecting misplaced ETTs with capnography, in the neonatal population. Capnography was associated with fewer cases of undetected ETT misplacements (<1% versus 2.2%) and costs were, on average, \$89 per patient compared to \$39 in the standard monitoring group. Due to the lack of evidence available in the present review, an assessment of the value of capnography for continuous monitoring of pediatric patients in serious or critical condition was not possible. The single costing study identified in the review of the economic literature, however, found differences in the utilization of blood gases before and after the implementation of standard continuous side stream capnography for all mechanically ventilated patients in the pediatric intensive care unit. This translated to a decline in annual total blood gas charge, ranging from \$2,207,804 to \$2,261,051 before the introduction of capnography to \$1,544,360 with the introduction of capnography. It should be noted that this costing study did not measure changes in patient outcomes following the introduction of capnography, and it did not include the upfront purchase and maintenance costs of the capnography device.

### *ETCO<sub>2</sub> monitoring for adult and pediatric patients with known obstructive sleep apnea or receiving high doses of opioids in post-operative care*

There was no evidence to assess the effectiveness of capnography compared to other forms of monitoring for the detection of respiratory failure for adult patients in post-operative care settings. For other clinical effectiveness outcomes, compared to standard monitoring, one study found that patients in the post-anesthesia care unit following orthopedic surgery who were monitored with capnography were more likely to have a respiratory event detected, and fewer pauses in breathing while sleeping.<sup>31</sup> These results, however, are difficult to interpret given that the study stated that the respiratory events were detected by respiratory rate changes or apnea detection and not by pulse oximetry or capnography. Compared to rainbow acoustic monitoring, patients monitored with capnography were statistically significantly less likely to have a respiratory pause detected.<sup>71</sup> Rainbow acoustic monitoring, however, does not measure ETCO<sub>2</sub>, and thus only provides part of the picture of a patient's ventilation status. Similar to the findings for adult patients in serious or critical condition, the limited clinical evidence led to an exploratory economic evaluation based on the assumption that the treatment effects of capnography compared to standard monitoring for the incidence of respiratory failure would be similar to what was observed in adult patients receiving procedural sedation. The results showed that capnography improved health outcomes at a lower cost for adults in post-operative care, and therefore dominated standard monitoring.

Opioids are commonly used in the post-operative period for the management of pain,<sup>122</sup> during which time opioid-induced respiratory depression is possible. For the two studies included in our review, 97%<sup>71</sup> and 100%<sup>31</sup> of patients were prescribed post-operative pain medication. The extent of patient monitoring is dependent on several factors such as the details of the procedure, patient comorbidities, presence and severity of sleep apnea, and the capabilities of the hospital facility.<sup>123</sup> These and other factors can increase a patient's risk for respiratory depression when opioids are administered.<sup>122</sup>

No clinical trials were identified on the use of capnography in pediatric patients in post-operative care and, as such, the clinical effectiveness and cost-effectiveness of capnography in this patient population remains unknown.

#### *Harms*

For studies that reported harms data there were no significant differences to note between capnography and other forms of ventilation monitoring. The use of capnography has been associated with the occurrence of false-positive results; however it is unclear how these events influence patient management and outcomes. False-positive events may result from the ingestion of carbonated beverages prior to monitoring,<sup>124</sup> from the displacement of the supplemental oxygen line,<sup>36</sup> or due to leaks in the sampling devices or ventilator circuit.<sup>5</sup> For example, in infants and neonates, uncuffed endotracheal tubes are often used to protect airways and there is the risk of leakage when this is done.<sup>101</sup> Patients may also experience ETCO<sub>2</sub> changes suggestive of respiratory depression but with no subsequent hypoxia, a finding apparent in several studies included in our review.<sup>53-55,125</sup> In the latter case, these changes may be due to false-positives, an intervention provided by the clinical team, or due to spontaneous resolution of the event. As a medical device that requires calibration, there may also be concerns about incorrect calibrations of the monitoring device, as was the case in the medical device recall of the Alaris ETCO<sub>2</sub> modules.<sup>126</sup>

## 7.2 Generalizability of Findings

Following the search criteria used for our clinical review, there were two systematic reviews,<sup>20,127</sup> one of which included a meta-analysis,<sup>20</sup> identified in the published literature to enable a comparison with our results. The meta-analysis assessed the effectiveness of capnography for detecting respiratory events in adult patients undergoing procedural sedation.<sup>20</sup> The results of this study are similar to those found in our review, indicating that the use of capnography in addition to standard monitoring resulted in greater detection of respiratory events. This study did not assess the impact of capnography monitoring on the occurrence of hypoxemia, changes in clinical management, or other outcomes of interest in our review. The other systematic review identified from the literature assessed the use of all forms of carbon dioxide monitoring for preterm newborns in the delivery room.<sup>127</sup> The review identified capnography as offering more timely and accurate confirmation of ETT placement compared to clinical assessment.<sup>128</sup> Our review however, was not meant to systematically assess the accuracy of capnography for detecting ETT placement. Two other systematic reviews,<sup>129,130</sup> one of which included a meta-analysis,<sup>129</sup> were identified that assessed the relationship between ET<sub>CO<sub>2</sub></sub> values and ROSC, with the goal of identifying an optimal ET<sub>CO<sub>2</sub></sub> value during CPR,<sup>129</sup> or as a prognostic indicator of outcome following CPR,<sup>130</sup> however these outcomes were not of interest in our review. While we recognize that a similar systematic review<sup>38</sup> was being undertaken at the same time as our HTA, the anticipated completion date and the project scope indicated in this protocol necessitated the need for our own review with shorter timelines and a broader scope.

Across patient populations, several clinical practice guidelines suggest that capnography should be used or should be considered for use in certain clinical situations. For patients undergoing procedural sedation, guidelines state that capnography should be considered for certain patients (RSS 4 to 6,<sup>6</sup> patients undergoing deep sedation,<sup>131,132</sup> where clinical assessment is not possible,<sup>132</sup> high risk patients,<sup>131</sup>) or procedures (long procedures,<sup>131</sup> patients undergoing laparoscopy for surgical problems during pregnancy).<sup>133</sup> In post-anaesthesia care units on the other hand, clinical practice guidelines suggest that pulse oximetry is the monitoring method of choice for patients during the initial phase of recovery,<sup>6</sup> for patients who are at increased risk of respiratory compromise,<sup>134</sup> and as a minimum addition to clinical monitoring in immediate post-anaesthesia.<sup>112</sup> Other guidelines suggest capnography be standard for healthcare procedures,<sup>135</sup> as an adjunct to pulse oximetry and clinical assessment for procedures in the emergency department,<sup>10</sup> be used according to the clinical status of the patient,<sup>136</sup> and as a minimum for patients undergoing bariatric surgery).<sup>123</sup> The establishment of guidelines and policies for the use of capnography has been found to be supportive of successful implementation.<sup>23,92,97,111</sup>

Capnography is also commonly the monitoring method of choice in clinical practice guidelines that apply to the management of patients who are intubated or are undergoing intubation. For patients undergoing CPR, capnography has been described as having application as a device to guide the placement of an ETT, monitor ventilation status, to guide the effectiveness of chest compressions, and to predict survival during resuscitation.<sup>25,26,137</sup> Several reviews and clinical practice guideline documents<sup>7,138,139</sup> have highlighted these applications. Clinical practice recommendations for intensive care services<sup>140</sup> and respiratory care<sup>5</sup> also recommend the use of capnography for all airway placements. The Canadian Pediatric Societies position statement on the interfacility transport of critically ill newborns suggest capnography devices (either end-tidal CO<sub>2</sub> or transcutaneous) be used as part of the suite of neonatal transport equipment,<sup>141</sup> and UK resuscitation council guidelines for newborn life support suggest that capnography in addition to clinical assessment is the most reliable method for confirming ETT placement in neonates with spontaneous circulation.<sup>142</sup>

The majority of the clinical evidence was from the USA, generally based at urban, tertiary care, or university-affiliated centres. A minority of studies were based in Germany, Denmark, Spain, Ireland, The Netherlands, Japan, Taiwan, and Israel. The generalizability of our results to less specialized centres or rural settings, particularly for patients undergoing CPR or in serious or critical condition is unknown. This may have further implications to the economic model if it is suspected that the baseline rates of respiratory events would differ between urban and rural settings. Furthermore, the majority of the cost inputs were obtained from Ontario sources and, when necessary, supplemented by costs from the USA. Sensitivity analyses indicated that the cost inputs used in the cost-effectiveness analysis did not have a particularly strong influence on the results, and thus the variance in costs that may exist across geographical regions may not be a particular concern in interpreting the cost-effectiveness of capnography. The availability of devices, education and training for users, ease of use, and organizational culture are factors that may support the successful implementation of capnography monitors and that may vary across regions. Although it is likely that similar monitoring practices would occur across geographical regions, the lack of evidence from the Canadian setting is an important limitation to note when interpreting the clinical and economic findings of our review.

The economic analyses overall highlighted a general trend that may be applicable to all patient populations included in the present review. One-way sensitivity analyses consistently showed that the economic value of capnography monitoring was most sensitive to the baseline risk of respiratory failure (for patients undergoing procedural sedation, in serious or critical condition, or in post-operative care) and survival (for patients undergoing CPR). For example, given that the costs of treating respiratory failure were greatest in patients in serious and critical conditions, it was observed that capnography would be the dominant strategy compared to no monitoring of  $\text{ETCO}_2$  status, regardless of willingness to pay threshold.

Drawing conclusions about whether combined monitoring would be considered cost-effective across all Canadian jurisdictions, based on the primary economic analysis, may be difficult. Firstly, there are no common cost-effectiveness thresholds for the incremental cost per respiratory failure avoided or survival gained to reference. Furthermore, the analysis that demonstrated capnography being a dominant intervention in adults in serious or critical condition was based on an assumption of transferability of the clinical effectiveness results from the clinical outcomes observed in adult patients receiving procedural sedation. This may in fact not hold true given differences in patient demographics and disease severity between these patient populations.

### **7.3 Study Limitations**

There were several challenges and limitations encountered during this review. Our primary outcome was defined in our review protocol as hypoxemia, defined by a pulse oximetry measure ( $\text{SpO}_2$ ) for which study-specific definitions were extracted and included in the analysis. Although this approach allowed for a greater breadth of included studies, several studies reported multiple measures of hypoxemia, and the thresholds of hypoxemia varied between studies. The criteria for hypoxemia and severe hypoxemia adopted by our review were selected in consultation with the clinical experts; however we recognize that these thresholds will vary between centres.

There was a limited amount of data available for several patient populations and outcomes, making it difficult to provide an indication of the direction for the favourability of evidence for these outcomes in each population of interest. The lack of clinical evidence in some

populations, also led to an economic evaluation with a narrower focus than anticipated, or, resulted in generalizing data from one clinical area to perform an exploratory analysis in another clinical area. The economic model for neonates in serious and critical condition, for example, could only address the use of capnography to ensure correct placement of the ETT and not the use of capnography for continuous monitoring of patients in intensive care. Furthermore, the parameters used in this model came from a study published in 1995<sup>143</sup> and it is questionable whether the performance of capnography has remained constant over time. The interpretation of the results of the economic evaluation presented in this review was also challenged by the lack of published literature to serve as a comparison.

Due to the heterogeneity between studies in terms of study design, intervention, comparator, patient characteristics, and procedure type (for procedural sedation and post-operative recovery), we were unable to assess the differential benefit of capnography for specific patient characteristics or clinical situations. Most devices used in the included studies were sidestream, portable, multiparameter models that were suitable for the adult, pediatric and neonatal populations; however there were an insufficient number of studies to assess the effectiveness of one capnography device compared to another.

While the inclusion of observational studies offered the ability to assess a greater breadth of outcomes, such as harms and adverse events, the inclusion of these studies also created challenges for the interpretation and synthesis of results. An additional challenge with the inclusion of observational studies was to understand that although a greater number of respiratory events may have been detected, we were unable to determine if the detection of respiratory events would have resulted in changes to clinical practice. Finally, we attempted to report as much detail as possible regarding the definition of standard monitoring for the included studies, however the specifics of standard monitoring were variable between studies and these details were often not reported or were unclear.

#### **7.4 Directions for Future Research**

Future research should assess the impact of capnography on the entire continuum of care for each of the four clinical populations included in our review. This research would help explain the clinical decision making pathway for each population and help recognize the links between detection of respiratory events, change in clinical management, incidence of respiratory failures, and clinically important endpoints such as morbidity and mortality. Comparative interventional research studies are needed for pediatric patients undergoing CPR and in post-operative recovery, and for adult patients in serious or critical condition and in post-operative recovery. A clearer picture of the clinical decision making pathway for each population and comparative evidence in each would inform a more complete decision analytic framework and generate more accurate inputs for the economic model. The establishment of levels of severity for hypoxemia (for example, mild, moderate, severe and profound), would help encourage consistent reporting across studies, and allow for a more objective assessment of study results. The systematic collection of harms data may help identify patient populations that are particularly susceptible to false alarms or technical problems with the monitoring device.

## **8 CONCLUSIONS**

The greatest volume of clinical evidence was available for the use of capnography in adult patients undergoing procedural sedation. In this population, respiratory events were detected more frequently with capnography and fewer patients experienced episodes of hypoxemia as compared to standard monitoring. These results, when transferred into the economic evaluation,

suggested that capnography offered more health benefit but at an additional cost. In this situation, which was also found for adult patients undergoing CPR, the interpretation of whether capnography is considered cost-effective is dependent on the opportunity cost of its adoption. If capnography is adopted for use for adult patients undergoing procedural sedation and CPR, resources must be extracted from within the health-care system or new funding must be found.

Capnography provided increased detection of misplaced ETT tubes in adult trauma patients, and increased detection of respiratory events in patients recovering from orthopaedic surgery. For adult patients in serious or critical condition and in post-operative care, capnography was the dominant intervention; however the economic analysis was an exploratory analysis based on the assumption that treatment effects would be consistent with what was observed in patients undergoing procedural sedation. Future research should assess the use of capnography in adults in serious or critical condition and in post-operative care.

The clinical and economic evidence for the use of capnography in pediatric patient populations is particularly limited. There was no evidence for pediatric patients undergoing CPR or in post-operative care, and the clinical evidence was mixed for the effectiveness of capnography in pediatric patients undergoing procedural sedation and in serious or critical condition. In pediatric patients in serious or critical condition, the use of capnography led to fewer undetected misplaced ETTs at a higher cost; the cost-effectiveness of capnography for use as a continuous monitor in this population is unknown. The clinical evidence for capnography compared to standard monitoring in pediatric patients undergoing procedural sedation suggested that there were no statistically significant differences in the risk of respiratory failure, or in changes to patient management that generate costs. Consequently, capnography was not found to be cost-effective in pediatric patients undergoing procedural sedation.

There was no evidence to suggest a difference in harms outcomes with the use of capnography compared to no monitoring or standard monitoring, however further research should assess the impact of the occurrence of false positive signals. Consideration of the barriers and supports of capnography across hospital and pre-hospital settings will allow for the most effective implementation. A lack of training and a lack of knowledge of capnography outputs and how to interpret the data to change the course of patient treatment may lead to lower adoption rates. If the technology and components are easily accessible, always available, and protocols for their use are in place, the greater the likelihood of achieving successful implementation.

<b>OTHER DATABASES</b>	
PubMed	A limited PubMed search was performed to capture records not found in MEDLINE. Same MeSH, keywords, limits, and study types used as per MEDLINE search, with appropriate syntax used.
Cochrane Library Issue 7, 2015	Same MeSH, keywords, and date limits used as per Medline search, excluding study types and Human restrictions. Syntax adjusted for Cochrane Library databases.

## Grey Literature

Dates for Search:	July to August 2015
Keywords:	Capnography, capnometry, ETCO <sub>2</sub> , carbon dioxide monitoring
Limits:	2005 to 2015

Relevant websites from the following sections of the CADTH grey literature checklist, "Grey matters: a practical tool for evidence-based searching" (<https://www.cadth.ca/grey-matters>) were searched:

- Advisories & Warnings
- Advocacy group, association
- Background
- Clinical Practice Guidelines
- Clinical Trial Listing
- Databases (free)
- Health Economics
- Health Technology Assessment Agencies
- Internet Search
- Open Access Journals
- Regulatory Approvals

## APPENDIX B: DETAILED METHODS AND RESULTS OF THE REVIEW OF ECONOMIC STUDIES

### 5.1.1 Methods

#### 5.1.1.1 Literature search strategy

The literature search was performed by an information specialist using a peer-reviewed search strategy.

Published literature was identified by searching the following bibliographic databases: MEDLINE with in-process records and daily updates via Ovid; Embase via Ovid; and PubMed. The search strategy consisted of both controlled vocabulary, such as the National Library of Medicine’s MeSH (Medical Subject Headings), and keywords. The main search concepts were capnography, capnometry, and carbon dioxide monitoring of patients undergoing CPR, procedural sedation, in serious or critical condition, with obstructive sleep apnea, or receiving high opioid doses post-operatively.

Methodological filters were applied to limit retrieval to economic studies. Retrieval was limited to English language documents published between January 1, 2005 and September 25, 2015. See Appendix A for the detailed search strategies. Regular alerts were established to update the search until the publication of the final report. Regular search updates were performed on databases that do not provide alert services.

Grey literature (literature that is not commercially published) was identified by searching the “Grey Matters” checklist ([www.cadth.ca/grey-matters](http://www.cadth.ca/grey-matters)), which includes the websites of health technology assessment agencies and other economics-related resources. Google and other Internet search engines were used to search for additional web-based materials, including conference abstracts. These searches were supplemented through contacts with appropriate experts and industry. See Appendix A for more information on the grey literature search strategy.

#### 5.1.1.2 Selection criteria

##### **Inclusion criteria**

Studies were eligible for inclusion in the systematic review if they met the criteria listed in Table 12 .

	<b>Research Questions 1 &amp; 2</b>	<b>Research Questions 3 &amp; 4</b>	<b>Research Questions 5 &amp; 6</b>	<b>Research Questions 7 &amp; 8</b>
<b>Population</b>	Adult (aged ≥18 years) and pediatric patients who are sedated for the purposes of tolerating an interventional or diagnostic procedure.	Adult (aged ≥18 years) and pediatric patients who are experiencing cardiac arrest and/or absent or abnormal breathing for which CPR is being performed.	Adult (aged ≥18 years) and pediatric patients who are in serious or critical condition where vital signs are either unstable or may be unstable and are not within normal limits.	Adult (aged ≥18 years) and pediatric patients receiving post-operative care with known obstructive sleep apnea and/or who are receiving high opioid doses.

**Table 12: Inclusion criteria for the economic review**

	Research Questions 1 & 2	Research Questions 3 & 4	Research Questions 5 & 6	Research Questions 7 & 8
<b>Intervention</b>	End-tidal CO <sub>2</sub> (ETCO <sub>2</sub> ) monitoring using capnography (alone or in combination with other monitoring equipment)			
<b>Comparators</b>	<ul style="list-style-type: none"> <li>- No ETCO<sub>2</sub> monitoring</li> <li>- Standard monitoring (e.g., pulse oximetry, pulse rate, blood pressure, visual assessment)</li> <li>- Capnography (comparing between alternative types, such as fixed or portable)</li> <li>- Capnometry</li> <li>- Exhaled CO<sub>2</sub> detector</li> <li>- Esophageal detector device (for patients who are intubated)</li> </ul>			
<b>Outcomes</b>	<ul style="list-style-type: none"> <li>- ICER: cost per unit of clinical outcome; cost per QALYs</li> <li>- Costs</li> </ul>			
<b>Study Setting</b>	in hospital	In hospital or pre-hospital settings <sup>a</sup>		in hospital
<b>Study Design</b>	Health technology assessment reports and economic evaluation studies (cost analysis, cost consequence analysis, cost minimization analysis, cost-effectiveness analysis, cost-utility analysis, cost-benefit analysis)			

CO<sub>2</sub> = carbon dioxide; CPR = cardiopulmonary resuscitation; ETCO<sub>2</sub> = end-tidal carbon dioxide; ICER = incremental cost effectiveness ratio; QALYs = quality adjusted life years

<sup>a</sup>Pre-hospital settings include care provided by health care providers as first responders and during ambulatory transport.

### **Exclusion criteria**

Studies were excluded if they did not include a defined population/condition or they were not published in English. Duplicate publications, abstracts/summaries, case studies, reviews, comments, letters, and editorials were also excluded.

### **Selection method**

Two reviewers (IA, CY) used the screening checklist in Table 13 to review the title and abstract of each citation. Full-text articles were obtained for citations that could not be excluded by title and abstract screening, and the full-text was assessed using explicit predetermined criteria (Table 14). Disagreements between reviewers were resolved by consensus, consulting a third reviewer when necessary.

**Table 13: Title and abstract screening checklist for the review of economic studies**

#### 5.1.1.3 Data extraction/abstraction strategy

One reviewer (IA) used a standard data extraction form to record relevant information, which was verified by a second reviewer (CY). The information collected include author, title, country, objective, population, setting, comparators, form of economic analysis, perspective, timeframe, clinical effectiveness data source, health and cost outcomes, data and decision modelling details, sensitivity analysis approach, currency and year, results from the marginal analysis, and conclusion.

#### 5.1.1.4 Strategy for quality assessment of the studies

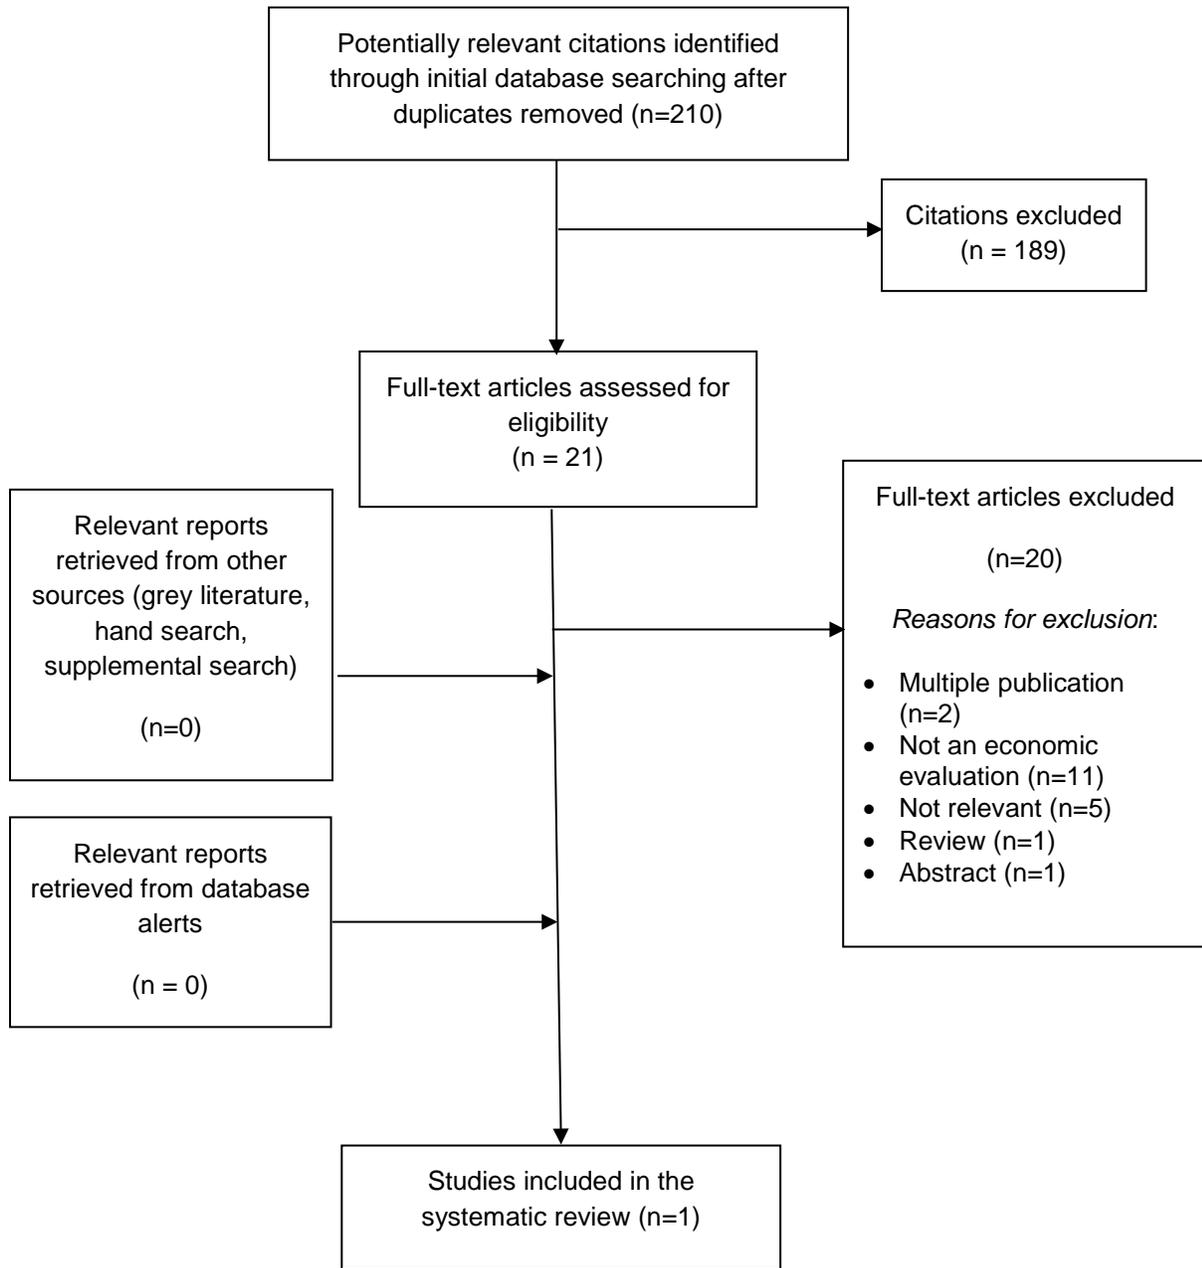

The quality of each included study was independently assessed by two reviewers (IA, CY) with the Drummond checklist.<sup>144</sup> Disagreements between reviewers were resolved by consensus, consulting a third reviewer when necessary.

### 5.1.2 Results

#### *5.1.2.1 Quantity of research available*

Of the 210 citations identified from the economic search, 20 were identified for further review. A total of 19 articles were excluded, resulting in one study that met the selection criteria ( $\kappa=1$ ). Figure 5 shows the PRISMA flowchart of the process used to identify and select studies for the review, as well as the main reasons for exclusion. Table 15 presents the list of excluded studies and the reasons for exclusion. The details of the included study are described in Table 16.

**Table 16: Description of the included study in the review of economic studies**

Study	Rowan et al. 2014 <sup>6</sup>
Objective	To determine if implementation of continuous capnography monitoring decreases the utilization of blood gases resulting in decreased charges.
Population	Mechanically ventilated patients in the pediatric intensive care unit (patients from the cardiac critical care service who received ETCO <sub>2</sub> monitoring were excluded)
Setting	United States, retrospective review
Comparators	Before and after the implementation of continuous side stream capnography (comparing the utilization of blood gases)
Form of economic analysis	Cost analysis
Perspective	Not stated
Timeframe	(1) April 2009 to September 2009 (before the implementation of capnography) (2) April 2010 to September 2010 (before the implementation of capnography) (3) April 2011 to September 2011 (after the implementation of capnography)
Clinical effectiveness data source	Total number of blood gas analyzed, ventilator, and patient days were taken from a 3-year period US study (data collected from clinical decision support)
Quality of life	NA
Direct costs	Cost savings from decreased number of blood gas analysis (data collected from hospital accounting)
Indirect costs	NA
Data modelling details	NA
Decision modelling details	NA
Sensitivity analysis approach	One-way ANOVA
Currency and year	US 2010
Important findings from sensitivity analysis	There was a statistically significant decrease in the total number of blood gases analyzed, and in the average number of blood gases analyzed per patient and per ventilator day after the institution of continuous ETCO <sub>2</sub> monitoring, compared to the same time period from the prior years.
Results	The total charge savings over a 6-month period was \$880,496.
Conclusions	Continuous capnography resulted in a significant savings over a 6-month period by decreasing the utilization of blood gas measurements.

ASA = American Association of Anesthesiology; CI = confidence interval; COPD = chronic obstructive pulmonary disease; CPAP = continuous positive airway pressure; CPR = cardiopulmonary resuscitation; ETCO<sub>2</sub> = end-tidal carbon dioxide; HR = hazard ratio; RCT = randomized controlled trial; RR = relative risk.

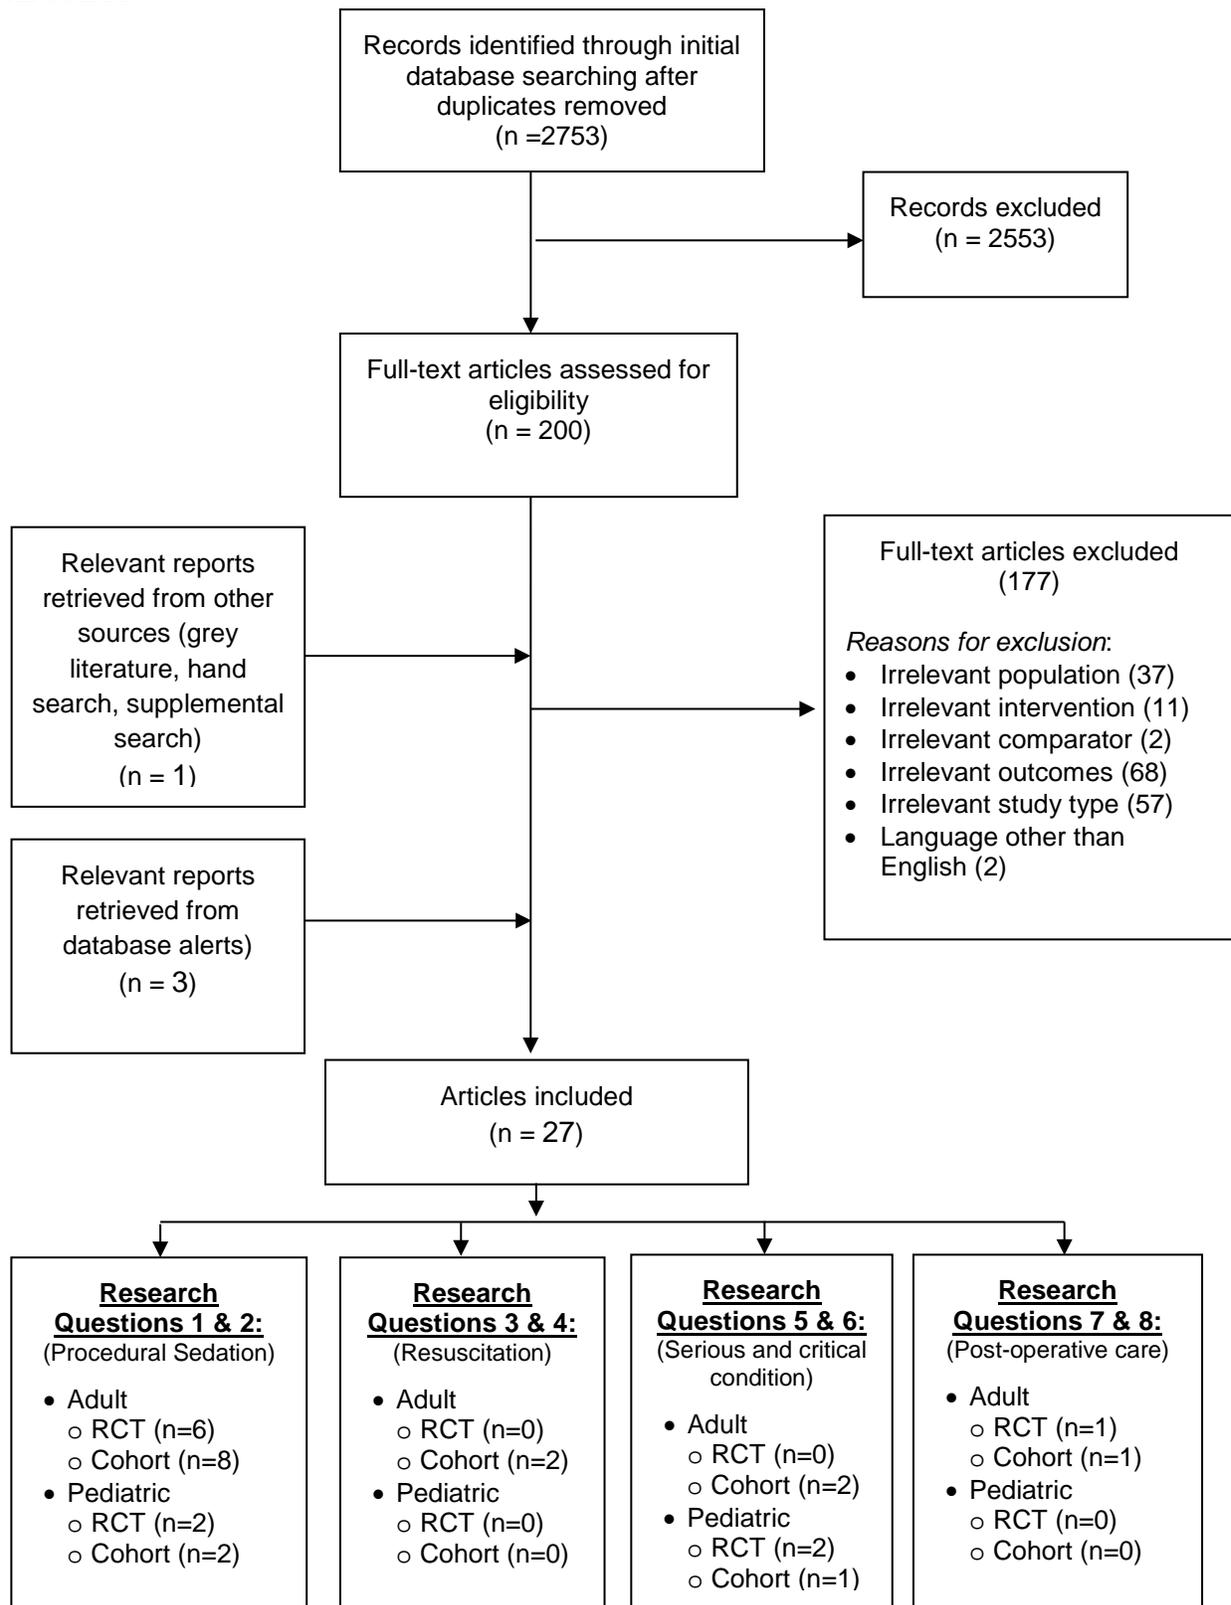

<sup>a</sup> Continuous outcomes.

<sup>b</sup> Research questions 1 and 2: detection of respiratory failure (hypoxemia or hypercapnia), detection of a respiratory event (i.e., hypoventilation, hyperventilation, apnea, airway obstruction), time to detection of a respiratory event, change in clinical management (i.e., re-evaluate patients, avoid use of more sedative). Research questions 3 and 4: survival of acute event, return of spontaneous circulation, effectiveness of chest compressions, detection of respiratory failure (hypoxemia, hypercapnia), change in clinical management (i.e., continue or withhold chest compressions, re-evaluate patients). Research questions 5 to 8: detection of respiratory failure (hypoxemia or hypercapnia), detection of a respiratory event (i.e., hypoventilation, hyperventilation, apnea, airway obstruction), time to detection of a respiratory event, change in clinical management (i.e., re-evaluate patients, provide airway support). All clinical research questions (1 to 8): survival to hospital discharge, discharge with full neurological functioning, hypoxemia, organ damage, ventilation variables, hemodynamic variables, length of stay in hospital, correct placement of endotracheal tube, displacement of ventilation or intubation tube, adverse events related to the capnography device (i.e., misinterpretation of capnography readings, capnography device malfunction).

<sup>c</sup> Binary or time to event outcomes.

Study	Strengths	Limitations
	<p>the randomization.</p> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>Analyses were completed for the ITT (though not including three patients who withdrew consent after randomization) and PP populations; reasons for patients lost to follow-up were documented.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>Primary outcome measure stated in the published paper was the same as what was reported in the clinicaltrials.gov record (NCT01072487).</li> </ul>	<ul style="list-style-type: none"> <li>Outcome assessors were not blind to patient allocation.</li> </ul> <p>Other biases</p> <ul style="list-style-type: none"> <li>Baseline imbalances between treatment groups for history of lung disease and oxygen saturation.</li> </ul>
Deitch 2010 <sup>18</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Method of randomization was described.</li> <li>Study personnel and treatment team were not involved in the randomization.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Before blinding was broken, three investigators evaluated the data to assess for the presence or absence of hypoxia and respiratory depression.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>Patients were excluded if there was &gt;35% data loss.</li> </ul>	<p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients and treatment team were not blinded to patient allocation.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol or clinicaltrials.gov record was found so the presence of reporting bias is unknown.</li> </ul> <p>Other limitations</p> <ul style="list-style-type: none"> <li>Not as many study participants were recruited as anticipated.</li> </ul>
Qadeer 2009 <sup>52</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Randomization was performed by the institutions biostatistics department.</li> <li>Concealed envelopes; assessors were not part of the randomization process.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>The endoscopy team was not aware of the capnography readings for either group of patients (the signal of capnography abnormalities was signaled by an independent investigator).</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>93.9% of patients were included in the efficacy analysis in both arms; reasons for exclusion were described.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No evidence of selective reporting based on the clinicaltrials.gov record.</li> </ul>	<p>Detection bias</p> <ul style="list-style-type: none"> <li>Primary outcome assessors (for hypoxemia) were not blind to patient allocation.</li> </ul>

ASA = American Association of Anesthesiology; ITT = intention to treat; NAPS = nurse-administered propofol sedation; PP = per-protocol; RCTs = randomized controlled trials; SpO<sub>2</sub> = arterial oxygen saturation measured by pulse oximetry

**Table 46: Critical appraisal of non-RCTs for adult patients undergoing procedural sedation**

Study	Strengths	Limitations	Overall assessment and author conclusions
Tanaka 2014 <sup>50</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined.</li> <li>All patients were continuously monitored with capnography.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>5% of patients did not complete the study.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>Confidence intervals were provided.</li> </ul>	<p><b>Adult prospective cohort studies</b></p> <p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to any patient exposure. No mention of lack of blinding potentially influencing outcome assessment.</li> <li>It is unclear if the study investigators were trained in identifying the outcome measures that were used.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul> <p>Other limitations</p> <ul style="list-style-type: none"> <li>Potential confounders were mentioned in the limitations section but it is unclear if they were considered for the analysis.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> No (considered a pilot study; results do not necessarily capture all true respiratory pauses because the retrospective review of data only looks at a minute before and a minute after the event that was detected by one of the interventions).</p> <p><b>Results applicable to the patient group targeted?</b> Yes</p> <p><b>Author conclusions:</b> Apnea and excessive sedation occur in patients undergoing monitored anesthetic care; acoustic monitoring provided the highest probability of detecting respiratory pause and the lowest probability of missing a respiratory pause. Acoustic monitoring may be the most effective option (versus capnography and clinical observation) for monitoring ventilation during procedural sedation.</p>
Schlag 2013 <sup>55</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined; references for the definition of the primary outcome were provided.</li> <li>All patients were continuously monitored with capnography.</li> <li>All study data and observations were recorded by an investigator who was not involved in patient care.</li> </ul> <p>Attrition bias</p>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to any patient exposure.</li> <li>It is unclear if the study investigators were trained in identifying the outcome measures that were used.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> No (small sample size, not intended to be an interventional study)</p> <p><b>Results applicable to the patient group targeted?</b> Yes (for adult patients undergoing procedural sedation for percutaneous transhepatic cholangidrainage).</p> <p><b>Author conclusions:</b> Authors found that capnography was more effective for capturing episodes of apnea, and predicting episodes of oxygen desaturation compared to standard monitoring and observation in patients undergoing procedural sedation for percutaneous transhepatic cholangidrainage. Authors recognized the limitations of study design, limited sample size.</p>

**Table 46: Critical appraisal of non-RCTs for adult patients undergoing procedural sedation**

Study	Strengths	Limitations	Overall assessment and author conclusions
	<ul style="list-style-type: none"> <li>No patients were lost to follow-up.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>		
Kusunoki 2012 <sup>56</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined.</li> <li>All patients were continuously monitored with capnography.</li> </ul> <p>Other biases</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to any patient exposure. No mention of lack of blinding potentially influencing outcome assessment.</li> <li>No discussion of the validity of SpO<sub>2</sub> for detecting hypoxia or references for its definition.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>Unclear if there was any missing data or if any patients were lost to follow-up.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> Can't say (results are suggestive of an association between ET<sub>CO<sub>2</sub></sub> and the ability to detect respiratory changes; however, due to the few number of events, the association is uncertain.)</p> <p><b>Results applicable to the patient group targeted?</b> Yes</p> <p><b>Author conclusions:</b> Authors concluded that ET<sub>CO<sub>2</sub></sub> values correlated with Pt<sub>CO<sub>2</sub></sub> values, and respiratory monitoring methods allowed earlier detection of hypoxia for patients under conscious sedation (when compared with transcutaneous methods).</p> <p><b>Other notes:</b> There were a small number of events and Pt<sub>CO<sub>2</sub></sub> monitoring did not identify any events so it is unclear if these results would be confirmed in a larger trial.</p>
De Oliveira 2010 <sup>51</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> <li>98% (40/41) patients who were approached for enrollment agreed to participate in the study.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined; rationale provided for the definition of hypoventilation.</li> <li>All patients were continuously monitored</li> </ul>	<p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to any patient exposure. No mention of lack of blinding potentially influencing outcome assessment.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> Yes (the results were consistent with other studies in the area. Anesthesia staff was blinded to transcutaneous capnography)</p> <p><b>Results applicable to the patient group targeted?</b> Yes (very specific target population: women undergoing hysteroscopy)</p> <p><b>Author conclusions:</b> Authors concluded that T<sub>c</sub>CO<sub>2</sub> was more sensitive than ET<sub>CO<sub>2</sub></sub> and may provide a better assessment of hypoventilation for women undergoing deep sedation. Very specific patient population and women were otherwise healthy.</p>

**Table 46: Critical appraisal of non-RCTs for adult patients undergoing procedural sedation**

Study	Strengths	Limitations	Overall assessment and author conclusions
	<p>with capnography.</p> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>One patient had missing data that was excluded from the analysis.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No indication of differences in outcomes between the published article and the clincialtrials.gov record (NCT00954733)</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>		
Cacho 2010 <sup>57</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined; references were provided for ETCO<sub>2</sub> and SpO<sub>2</sub>.</li> <li>All patients were continuously monitored with capnography.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to any patient exposure. No mention of lack of blinding potentially influencing outcome assessment.</li> <li>It was not stated if the study investigators were trained in the outcome measures used.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>No mention of missing data.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Low Quality (0)</p> <p><b>Clear evidence of association between exposure and outcome?</b> No (methodology unclear; not clear the actual number of episodes of disordered respiration)</p> <p><b>Results applicable to the patient group targeted?</b> Yes (patients undergoing colonoscopy with sedation)</p> <p><b>Author conclusions:</b> Authors conclude that capnography is a useful compliment to patient monitoring based on visual assessment and pulse oximetry in patients undergoing colonoscopies with sedation. Authors also state that capnography allows for earlier detection of respiratory abnormalities and is more sensitive in detecting these abnormalities.</p>
Deitch 2008 <sup>53</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> <li>Patients were enrolled 24 hours/day, 7 days/week.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at</li> </ul>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to patient exposure.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> No (the study was not designed to assess the effects of ETCO<sub>2</sub> monitoring; the assessment of the use of capnography for identifying patients who may become hypoxic was a secondary objective.)</p> <p><b>Results applicable to the patient group targeted?</b> Yes</p>

**Table 46: Critical appraisal of non-RCTs for adult patients undergoing procedural sedation**

Study	Strengths	Limitations	Overall assessment and author conclusions
	<p>enrollment.</p> <ul style="list-style-type: none"> <li>All patients were monitored with ETCO<sub>2</sub> but physicians were blinded to the monitoring data.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined; validated outcome measures were used.</li> <li>Authors recognize that where blinding was not possible, the outcome assessors having knowledge of patient exposure status could have influenced the outcome.</li> <li>ETCO<sub>2</sub> was recorded at baseline and every 5 minutes until the patient returned to baseline alertness.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>No patients were lost to follow-up.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>		<p>(patients undergoing procedural sedation with propofol)</p> <p><b>Author conclusions:</b> The authors conclude that the use of capnography allowed for the detection of respiratory depression that was otherwise undetected by the clinical care team.</p> <p><b>Other notes:</b> Although capnography was found to detect a greater number of episodes of respiratory depression, it is uncertain how this would change patient outcomes because the clinicians were blinded to the ETCO<sub>2</sub> monitor. It is also noticeable that not all cases of respiratory changes that were detected by capnography led to a hypoxic event.</p>
Deitch 2007 <sup>54</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> <li>Patients were enrolled 24 hours/day, 7 days/week.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> <li>All patients were monitored with ETCO<sub>2</sub> but physicians were blinded to the monitoring data.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined.</li> <li>Authors recognize that where blinding was not possible, the outcome assessors having knowledge of patient exposure status could have influenced</li> </ul>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcome assessor was not blind to patient exposure.</li> <li>No references or rationale was provided for outcomes.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> No (the study was not designed to assess the effects of ETCO<sub>2</sub> monitoring; the assessment of the use of capnography for identifying patients who may become hypoxic was a secondary objective.)</p> <p><b>Results applicable to the patient group targeted?</b> Yes (patients undergoing procedural sedation and analgesia with midazolam and fentanyl)</p> <p><b>Author conclusions:</b> The authors conclude that the use of capnography allowed for the detection of respiratory depression that was otherwise undetected by the clinical care team.</p> <p><b>Other notes:</b> Although capnography was found to detect a greater number of episodes of respiratory depression, it is</p>

**Table 46: Critical appraisal of non-RCTs for adult patients undergoing procedural sedation**

Study	Strengths	Limitations	Overall assessment and author conclusions
	<p>the outcome.</p> <ul style="list-style-type: none"> <li>ETCO<sub>2</sub> was recorded at baseline and every 5 minutes until the patient returned to baseline alertness.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>No patients were lost to follow-up.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>		<p>uncertain how this would change patient outcomes because the clinicians were blinded to the ETCO<sub>2</sub> monitor. It is also noticeable that not all cases of respiratory changes that were detected by capnography led to a hypoxic event.</p>
Burton 2006 <sup>48</sup>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Only one group of patients was selected for inclusion – no differences between groups.</li> </ul> <p>Performance bias</p> <ul style="list-style-type: none"> <li>Patients were recruited prior to the start of the procedure – no outcome at enrollment.</li> <li>Patients and treatment team was blinded to monitoring data.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>Outcomes were clearly defined; definition of ETCO<sub>2</sub> change was provided.</li> <li>Study data and observations were recorded by an investigator who was not involved in patient care.</li> <li>All patients were continuously monitored with capnography.</li> </ul> <p>Attrition bias</p> <ul style="list-style-type: none"> <li>No patients were lost to follow-up.</li> </ul> <p>Other strengths</p> <ul style="list-style-type: none"> <li>All patients were monitored with capnography and standard monitoring – known and unknown confounders balanced in making comparisons.</li> </ul>	<p>Selection bias</p> <ul style="list-style-type: none"> <li>Patients were only recruited when the study investigator was present.</li> <li>No indication of the number of patients approached who did not consent.</li> </ul> <p>Detection bias</p> <ul style="list-style-type: none"> <li>It was not stated if the study investigators were trained in the outcome measures used.</li> </ul> <p>Reporting bias</p> <ul style="list-style-type: none"> <li>No protocol available.</li> </ul>	<p><b>How well did the study minimize bias?</b> Acceptable (+)</p> <p><b>Clear evidence of association between exposure and outcome?</b> Can't say (the study was terminated based on an interim safety analysis that ETCO<sub>2</sub> predicted respiratory events prior to oxygen saturation monitoring).</p> <p><b>Results applicable to the patient group targeted?</b> Yes</p> <p><b>Author conclusions:</b> The authors conclude that capnography allowed for the earlier detection of acute respiratory events compared to changes in pulse oximetry, and events detected by clinical observation of hypoventilation and apnea. The authors also recognize that the early recognition of acute respiratory events by ETCO<sub>2</sub> does not necessarily translate into a clinically meaningful event, and does not necessarily suggest that a change in clinical management would lead to a clinical improvement in respiratory status of the patient.</p> <p><b>Other notes:</b> The study was terminated early based on the understanding that ETCO<sub>2</sub> was detecting respiratory events prior to other forms of monitoring. This is suggestive of an effect, but the study was not completed.</p>

ETCO<sub>2</sub> = end tidal carbon dioxide; PtCO<sub>2</sub> = transcutaneous carbon dioxide; RCTs = randomized controlled trials; SpO<sub>2</sub> = arterial oxygen saturation measured by pulse oximetry; TcCO<sub>2</sub> = transcutaneous carbon dioxide

**Research Question 2: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing procedural sedation**

NR = not reported; O<sub>2</sub> = oxygen

<sup>a</sup>Apnea was defined by capnographic criteria (ETCO<sub>2</sub> = 0 for > 10 secs) or Bradypnea (< 8 breaths/min).<sup>19</sup>

<sup>b</sup>Apnea was defined by capnographic criteria only (absence of ETCO<sub>2</sub> or altered ventilation (reduction of ETCO<sub>2</sub> of more than half of baseline)).<sup>37</sup>

<sup>c</sup>Respiratory depression was defined by capnographic criteria only (ETCO<sub>2</sub> > 50mmHg, ETCO<sub>2</sub> change from baseline ≥ 10%, waveform loss ≥ 15 seconds); Difference between groups: 1% (95% -16 to 17).<sup>18</sup>

<sup>d</sup>The treatment team in the intervention arm was signalled by an independent observer of abnormalities within 5 to 10 seconds of appearance on the capnography monitor (included a flat waveform for > 5 seconds, >75% reduction in waveform amplitude compared to baseline, or respiratory rate of < 8 breaths/min). The treatment team of the control group was signalled for prolonged apnea (> 30 seconds).<sup>52</sup>

<sup>e</sup>Apnea was defined by capnographic criteria (flat capnographic waveform  $\geq$  15 seconds) or absence of respiratory activity.<sup>52</sup>

<sup>f</sup>Abnormal ventilation was defined by capnographic criteria only (flat capnographic waveform for  $\geq$  5 seconds and < 15 seconds or >75% reduction in waveform amplitude compared to baseline for  $\geq$  5 seconds).<sup>52</sup>

<sup>g</sup>Apnea was defined by capnographic criteria (decrease of exhaled partial pressure of CO<sub>2</sub> <8 mm Hg for  $\geq$ 15 seconds) and clinically as the cessation of breathing as observed by the physician.<sup>55</sup>

<sup>h</sup>Hypoventilation was defined by capnography criteria only (ETCO<sub>2</sub>  $\geq$  25% higher than baseline).<sup>57</sup>

<sup>i</sup>Apnea was defined as the cessation of breathing for  $\geq$ 30 secs.<sup>57</sup>

<sup>j</sup>Number of respiratory abnormalities events detected by capnography (intervention) compared to pulse oximetry (control).<sup>57</sup>

<sup>k</sup>Defined by capnographic criteria (ETCO<sub>2</sub> > 50 mm Hg, ETCO<sub>2</sub> >10 mmHg change from baseline, loss of waveform), SpO<sub>2</sub> (<93%) or by clinical detection (verbal indication from treatment team that the patient was experiencing respiratory depression, or the treating team provided an intervention to assist breathing).<sup>53</sup>

<sup>l</sup>Acute respiratory event defined as SpO<sub>2</sub>  $\leq$  92% and clinical interventions (increase supplemental oxygen, ventilation assistance, airway re-alignment, verbal or physical stimulation, use of reversal agents).<sup>48</sup>

<sup>m</sup>In 14 of the 17 patients with acute respiratory events, ETCO<sub>2</sub> abnormalities were detected before changes in pulse oximetry and clinical observation.<sup>48</sup>

Chen 2015 <sup>65</sup>	Return of spontaneous circulation <sup>a</sup>	Not stated	15	53	28.3	150	1060	14.2	NR <sup>b</sup>

ETCO<sub>2</sub> = end tidal carbon dioxide; NR = not reported

<sup>a</sup>sustained return of spontaneous circulation

<sup>b</sup>OR 2.39 (1.29–4.46); RD 0.14 (0.02–0.26)

**Table 69: Respiratory events detected for the included study (capnography versus chest wall impedance)**

Study	Definition	Primary or Secondary outcome	Intervention			Comparator			P value
Prospective cohort study (adult patients)									
			Capnography annotation			CWI annotation			
			All patients were monitored using capnography and CWI						
			n	N	%	n	N	%	
Edelson 2010 <sup>64</sup>	Hyperventilation (> 10 ventilations/min)	Not stated	30	35	86	28	35	81	0.44

CWI = chest wall impedance; n = number of events detected by the intervention or comparator; N = total number of events detected by the gold standard (manual annotation of capnography and CWI waveform data).

**Table 70: Survival to hospital discharge (capnography versus no capnography)**

Study	Definition	Primary or Secondary outcome	Intervention			Comparator			P value
Retrospective cohort study (adult patients)									
			Documented use of ETCO <sub>2</sub>			No documented use of ETCO <sub>2</sub>			
			n	N	%	n	N	%	
Chen 2015 <sup>65</sup>	Survival to hospital discharge <sup>a</sup>	Not stated	1	53	1.9	22	1060	2.1	0.924 <sup>b</sup>

ETCO<sub>2</sub> = end tidal carbon dioxide

<sup>a</sup>survival to hospital discharge was defined as a patient having had a record of survival to discharge.

<sup>b</sup>Reported odds ratio was 0.91 (0.12–6.90)

**Table 71: Adverse events reported in the included study (capnography versus chest wall impedance)**

Study	Definition	Primary or Secondary outcome	Intervention			Comparator			P value
Prospective cohort study (adult patients)									
			Capnography annotation			Chest wall impedance (CWI) annotation			

			All patients were monitored using capnography and CWI						
			n	N	%	n	N	%	
Edelson 2010 <sup>64</sup>	Data uninterpretable	Not stated	NR	37	9.7	NR	37	19.5	NR

CWI = chest wall impedance; n = number of resuscitation attempts that had uninterpretable data; N = number of resuscitation attempts; NR = not reported

**Research Question 4: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients undergoing CPR**

No data available.

**Research Question 5: Clinical effectiveness of ETCO<sub>2</sub> monitoring for adult patients in serious or critical condition**

**Table 72: Survival related outcomes reported in the included studies (capnography versus no capnography)**

Study	Definition	Primary or Secondary outcome	Intervention			Comparator			OR (95% CI)
			n	N	%	n	N	%	
Retrospective cohort study (adult patients)									
			Capnography			No capnography			
			n	N	%	n	N	%	
Bhat 2014 <sup>66</sup>	Mortality <sup>a</sup>	Not stated	NR	10	NR	NR	159	NR	<0.001 (<0.001, >100)

NR = not reported; OR = odds ratio

<sup>a</sup>Time point of assessment not specified.

**Table 73: ETT placement outcomes reported for the included studies (capnography versus no capnography)**

Study	Definition	Primary or Secondary outcome	Intervention			Comparator			P value
			n	N	%	n	N	%	
Prospective cohort study (adult patients)									
			Capnography			No capnography			
			n	N	%	n	N	%	
Silvestri 2005 <sup>67</sup>	unrecognized misplaced endotracheal tube	Primary	0	93	0	14	60	23.3	NR <sup>a</sup>
	death due to unrecognized improper tube placement	Not stated	0	93	0	9	60	15	NR

NR = not reported

<sup>a</sup>Odds of unrecognized misplaced intubation was higher in the comparator group versus the intervention group: OR 28.6 (95% CI 4.0 to 122.0)

**Research Question 6: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients in serious or critical condition**

**Table 74: Respiratory failure related outcomes reported in the included studies (capnography versus standard monitoring)**

Study	Definition	Primary or Secondary	Intervention	Comparator	P value
-------	------------	----------------------	--------------	------------	---------

		outcome							
Randomized study (pediatric patients)									
			Standard monitoring + capnography visible			Standard monitoring + capnography not visible			
			n	N	%	n	N	%

NA = not available; NR = not reported

**Research Question 8: Clinical effectiveness of ETCO<sub>2</sub> monitoring for pediatric patients with known sleep apnea or receiving high doses of opioids in post-operative care**

No Data available.

## APPENDIX L: CLINICAL AND COST INPUTS FOR THE ECONOMIC MODEL

**Table 85: Clinical inputs for each clinical condition in the adult population (primary analysis)**

Variable	Input	Range		Distribution	Source
		Low limit	High limit		
<b>Sedation – Adults</b>					
Proportion of patients who experience respiratory event(s)	58.27%	46.61%	69.92%	Beta ( $\alpha=451$ ; $\beta=323$ )	Clinical review
Respiratory failure (progressing due to respiratory event): mainly hypoxemia ( $\text{PaO}_2 < 8.0$ kPa or $< 60$ mm Hg) but also hypercapnia					
SM	26.81%	21.45%	32.17%	Beta ( $\alpha=352$ ; $\beta=961$ )	Clinical review
Capnography (RR compared to SM)	0.68	95% CI: 0.56 to 0.82		Lognormal	Clinical review
Survival to hospital discharge	100.00%			None	Clinical review
Discharge w/ organ damage	0.00%			None	Clinical review
Rate of ventilation assistance					
SM	8.51%	6.81%	10.21%	Beta ( $\alpha=16$ ; $\beta=172$ )	Clinical review
Capnography (RR compared to SM)	0.58	95% CI: 0.26 to 1.28		Lognormal	Clinical review
Supplemental oxygen					
SM	72.92%	58.34%	87.50%	Beta ( $\alpha=237$ ; $\beta=88$ )	Clinical review
Capnography (RR compared to SM)	0.93	95% CI: 0.73 to 1.20		Lognormal	Clinical review
<b>CPR – Adults</b>					
Probability of correct ETT placement <sup>a</sup>	93.00%	89%	97%	Beta	Takeda 2003, <sup>145</sup> Grmec 2002 <sup>146</sup>
Undetected ETT misplacements (i.e., false negatives)					
Capnography	0.00%			None	Grmec 2002 <sup>146</sup>
SM	0.00%	0	0.2 <sup>a</sup>	None	Grmec 2002 <sup>146</sup>
Survival given undetected ETT misplacement	0.00%				Assumption
Probability of survival of acute event (i.e., return to spontaneous circulation)					
Capnography	28.3%	22.6%	34.0%	Beta ( $\alpha=15$ ; $\beta=38$ )	Chen, 2015; <sup>147</sup> Phelan 2013 <sup>79</sup>
SM	14.2%	11.4%	17.0%	Beta ( $\alpha=150$ ; $\beta=910$ )	Chen, 2015; <sup>147</sup> Phelan 2013 <sup>79</sup>
Probability of survival to hospital discharge					
Capnography	1.9%	1.5%	2.3%	Beta ( $\alpha=1$ ; $\beta=52$ )	Chen, 2015; <sup>147</sup> Phelan 2013 <sup>79</sup>
SM	2.1%	1.7%	2.5%	Beta ( $\alpha=22$ ; $\beta=1028$ )	Chen, 2015; <sup>147</sup> Phelan 2013 <sup>79</sup>
Probability of discharge w/ organ damage <sup>a</sup>	10.70%	8.56%	12.84%	Beta	Girotra 2012 <sup>148</sup>

CI = confidence interval; ETT = endotracheal tube; RR = relative risk; SM = standard monitoring

<sup>a</sup>The high and low ranges for this parameter were based on  $\pm 20\%$  of the mean.

**Table 86: Clinical inputs for each clinical condition in the adult population (exploratory analysis)**

Variable	Input	Range		Distribution	Source
<b>Serious and critical condition – Adults</b>					
Probability of correct ETT placement <sup>a</sup>	92.00%	73.60%	100.00%	Beta ( $\alpha=274$ ; $\beta=23$ )	Schwartz 1995 <sup>149</sup>
Undetected ETT misplacements (i.e., false negatives)					
SM	23.00%	13.40%	36.00%	Beta ( $\alpha=14$ ; $\beta=46$ )	Silvestri, 2005 <sup>67</sup>
Capnography	0.00%				Silvestri, 2005 <sup>67</sup>
Survival given undetected ETT misplacement	35.71%	28.57%	42.86%	Beta ( $\alpha=5$ ; $\beta=9$ )	Silvestri 2005 <sup>67</sup>
Organ damage in those alive with ETT misplacement	40.00%	32.00%	48.00%	Beta ( $\alpha=2$ ; $\beta=3$ )	Silvestri 2005 <sup>67</sup>
Proportion of patients who experience respiratory event(s) <sup>b</sup>	58.27%	30.00%	90.00%	Beta ( $\alpha=451$ ; $\beta=323$ )	GS
Respiratory failure (progressing due to respiratory event): mainly hypoxemia ( $\text{PaO}_2 < 8.0$ kPA or $< 60$ mm Hg) but also hypercapnia					
SM	20.85%	16.68%	25.02%	Beta ( $\alpha=741$ ; $\beta=2813$ )	Thomas 2014 <sup>150</sup>
Capnography (RR compared to SM) <sup>c</sup>	0.68	0.1	0.9	Lognormal	GS
Survival to hospital discharge <sup>d,e</sup> <small>Assumed no difference between monitoring modalities, as per clinical review</small>	41.00%	32.80%	49.20%	Beta	Luhr 1999 <sup>151</sup>
Discharge w/ organ damage	0.00%			None	Silvestri 2005 <sup>67</sup>
Rate of ventilation assistance					
SM	8.51%	6.81%	10.21%	Beta ( $\alpha=16$ ; $\beta=172$ )	GS
Capnography (RR compared to SM)	0.58	95% CI: 0.26 to 1.28		Lognormal	GS
Supplemental oxygen					
SM	72.92%	58.34%	87.50%	None	GS
Capnography (RR compared to SM)	0.93	95% CI: 0.73 to 1.20		Lognormal	GS
<b>Post-operative care – Adults</b>					
Proportion of patients who experience respiratory event(s)	51.70%	41.36%	62.04%	Beta ( $\alpha=15$ ; $\beta=14$ )	Hutchison 2008 <sup>31</sup>
Critical respiratory event (defined as Hb oxygen saturation $< 90\%$ , respiratory rate $< 8$ breaths, upper airway obstruction)					
SM <sup>e</sup>	3.85%	0.80%	6.90%	Beta	Karcz 2013 <sup>152</sup>
Capnography (RR compared to SM) <sup>c</sup>	0.68	0.1	0.9	Lognormal	GS
Survival to hospital discharge	99.10%	79.28%	100%	Beta (322, 3)	Rose 1994 <sup>153</sup>
Discharge w/ organ damage	0.00%			None	GS
Rate of ventilation assistance					
SM	24.60%	19.68%	29.52%	Beta (80, 245)	Rose 1994 <sup>153</sup>
Capnography (RR compared to SM)	0.58	95% CI: 0.26 to 1.28		Lognormal	GS
Supplemental oxygen					

SM	59.70%	47.76%	71.64%	Beta (194, 131)	Rose 1994 <sup>153</sup>
Capnography (RR compared to SM)	0.93	95% CI: 0.73 to 1.20		Lognormal	GS

CI = confidence interval; ETT = endotracheal tube; Hb = hemoglobin; RR = relative risk; SM = standard monitoring; GS = data generalized from adult patients receiving procedural sedation

<sup>a</sup>range assumed to test capnography benefit in detecting ETT misplacement

<sup>b</sup>assume wider range from 46.61 to 69.92%, to, 30 to 90% to test impact in sensitivity analysis.

<sup>c</sup>assume wider range from (95% CI 0.56 to 0.82) to (0.1 to 0.9) to test impact in sensitivity analysis.

<sup>d</sup>90-day mortality converted to 30-day mortality.

<sup>e</sup>The high and low ranges for this parameter were based on  $\pm 20\%$  of the mean

**Table 87: Clinical inputs for each clinical condition in the pediatric population**

Variable	Input	Range		Distribution	Source
<b>Sedation – Pediatrics</b>					
Proportion of patients who experience respiratory event(s)	46.75%	37.40%	56.10%	Beta ( $\alpha=36$ ; $\beta=41$ )	Langhan 2011 <sup>74</sup>
Respiratory failure (progressing due to respiratory event): mainly hypoxemia ( $\text{PaO}_2 < 8.0$ kPa or $< 60$ mm Hg) but also hypercapnia					
SM	12.07%	9.66%	14.48%	Beta ( $\alpha=7$ ; $\beta=51$ )	Langhan 2011 <sup>74</sup>
Capnography (RR compared to SM)	1			None	Assumption (based on clinical review)
Survival to hospital discharge	100.00%			None	Assumption
Discharge w/ organ damage	0.00%			None	Assumption
<b>Serious and critical condition – Neonates</b>					
Probability of correct ETT placement	73.30%	58.64%	87.96%	Beta (33,12)	Aziz 1999 <sup>154</sup>
Undetected ETT misplacements (i.e., false negatives)					
SM	8.33%	6.67%	10.00%	Beta (5,55)	Roberts 1995 <sup>143</sup>
Capnography	2.50%	2.00%	3.00%	Beta (1,39)	Roberts 1995 <sup>143</sup>

ETT = endotracheal tube;  $\text{PaO}_2$  = partial pressure of oxygen; RR = relative risk; SM = standard monitoring

**Table 88: Cost inputs for each population (in 2015 \$)**

Item	Cost	Low limit	High limit	SD	Distribution	Source

BC = British Columbia; CPR = cardiopulmonary resuscitation; O<sub>2</sub> = oxygen; OCCI = Ontario Case Costing Initiative; SCC = serious or critical condition; SD = standard deviation

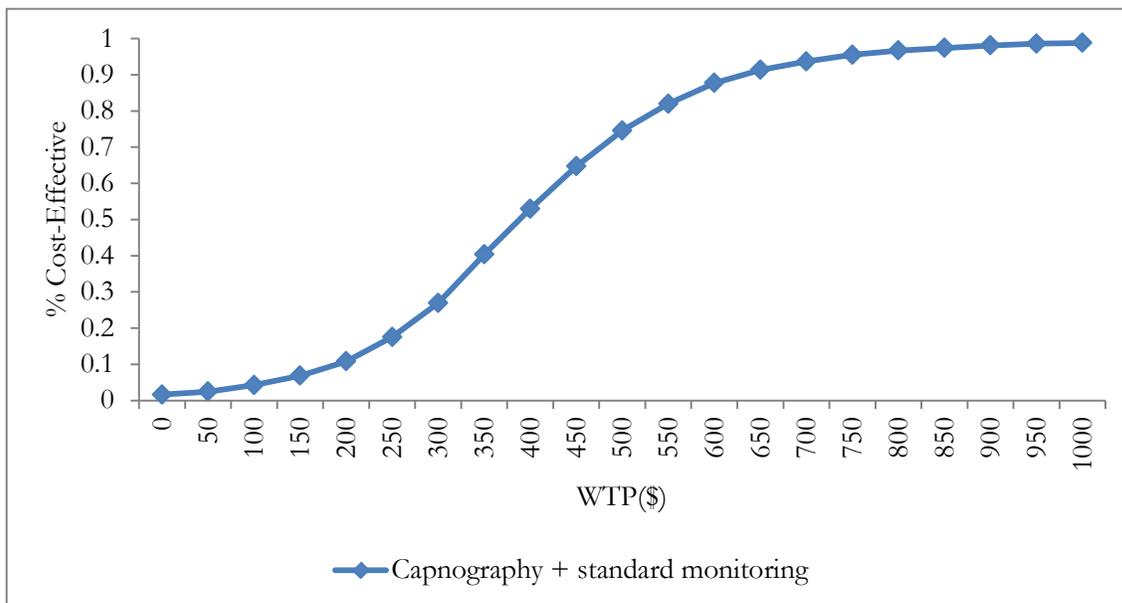

<sup>a</sup>Richard Milo, personal communication, 2015 Nov

<sup>b</sup>This included annual cost of hospital emergency department, acute care, and physician services for treatment of non-traumatic brain injury.

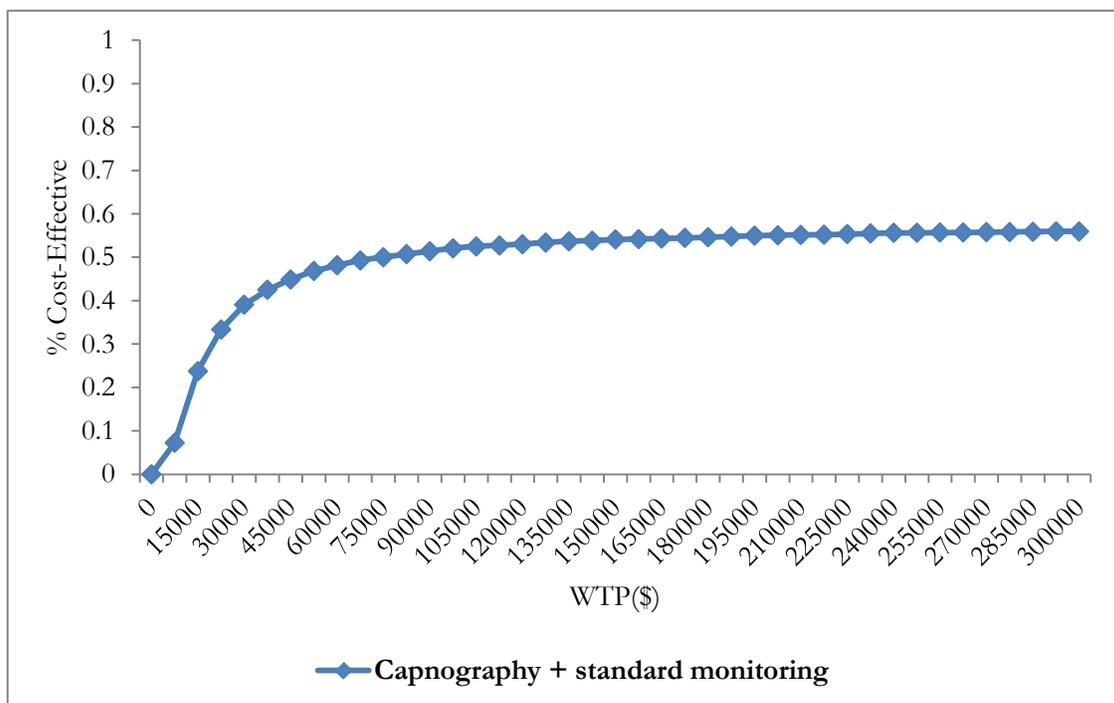

<sup>c</sup>Fee schedule refers to the Ontario schedule of benefits for physician services.

## APPENDIX M: DETAILED ECONOMIC RESULTS

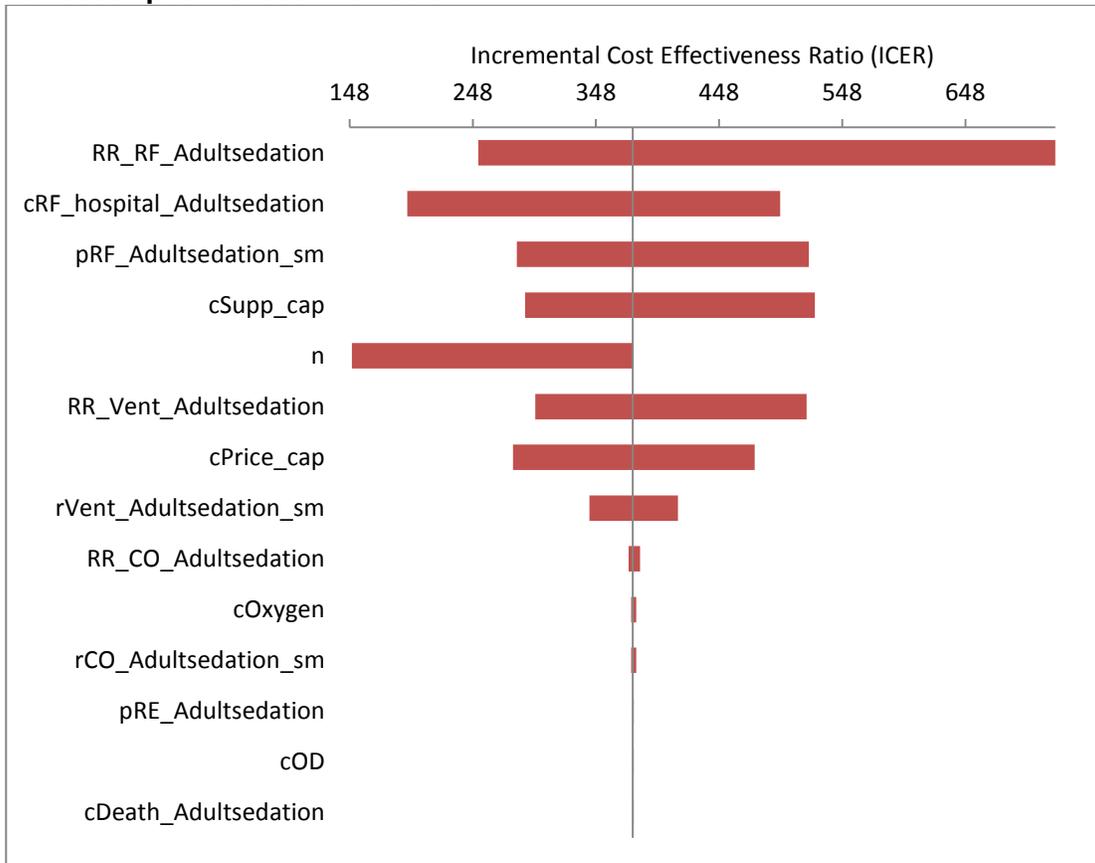

**Figure 10: Cost-effectiveness acceptability curve of capnography with standard monitoring, adult patients undergoing procedural sedation**

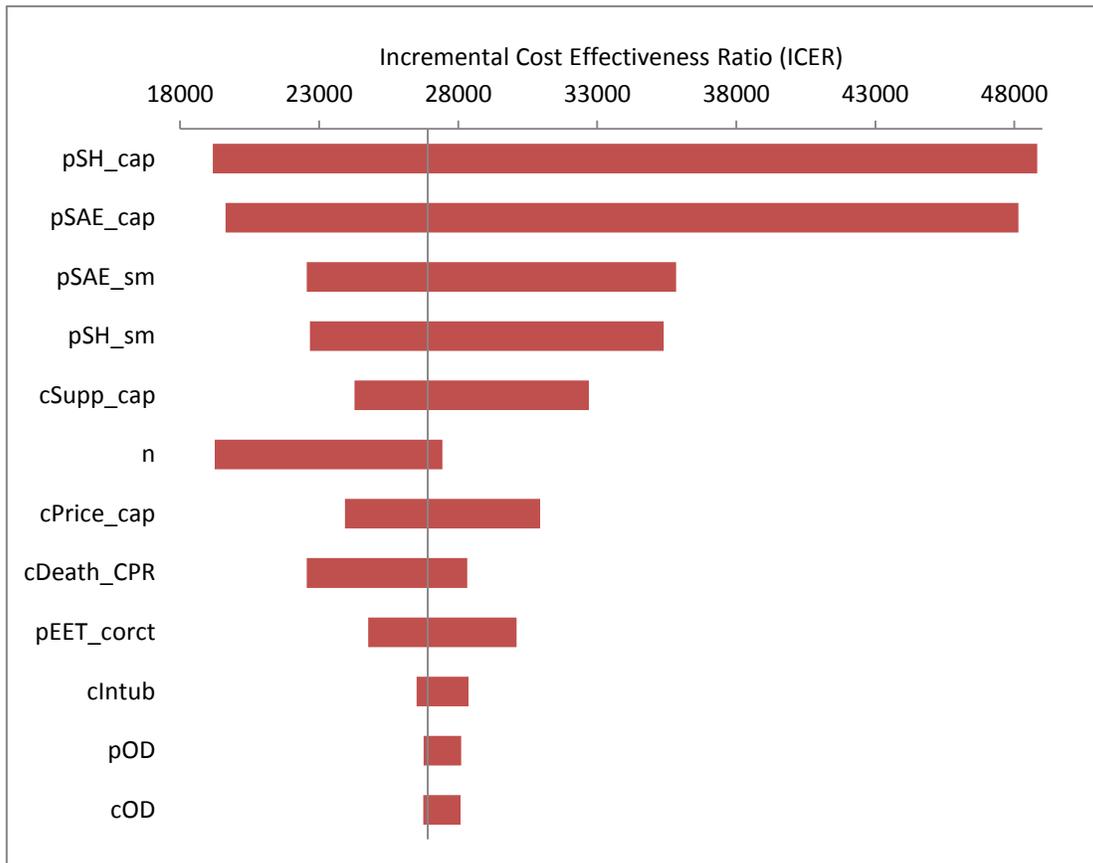

**Figure 11: Cost-effectiveness acceptability curve of capnography with standard monitoring, adult patients undergoing CPR (using data from Chen et al.<sup>65</sup>)**

**Figure 12: Tornado diagram, adult patients undergoing procedural sedation. See Table 89 below for description of each variable**

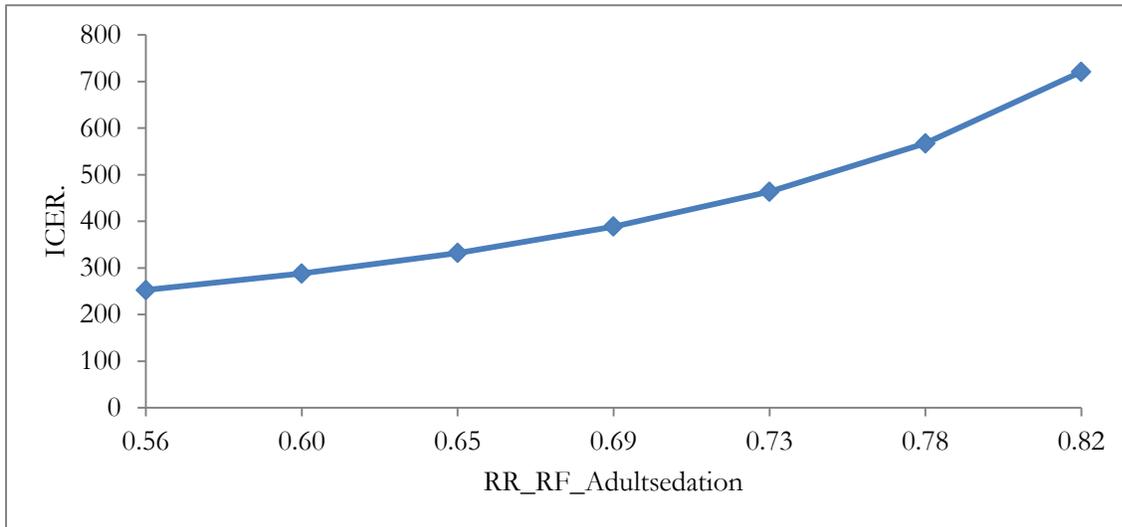

**Figure 13: Tornado diagram, adult patients undergoing CPR. Negative ICERs represent situation in which capnography is dominated by standard monitoring. See Table 89 below for description of each variable**

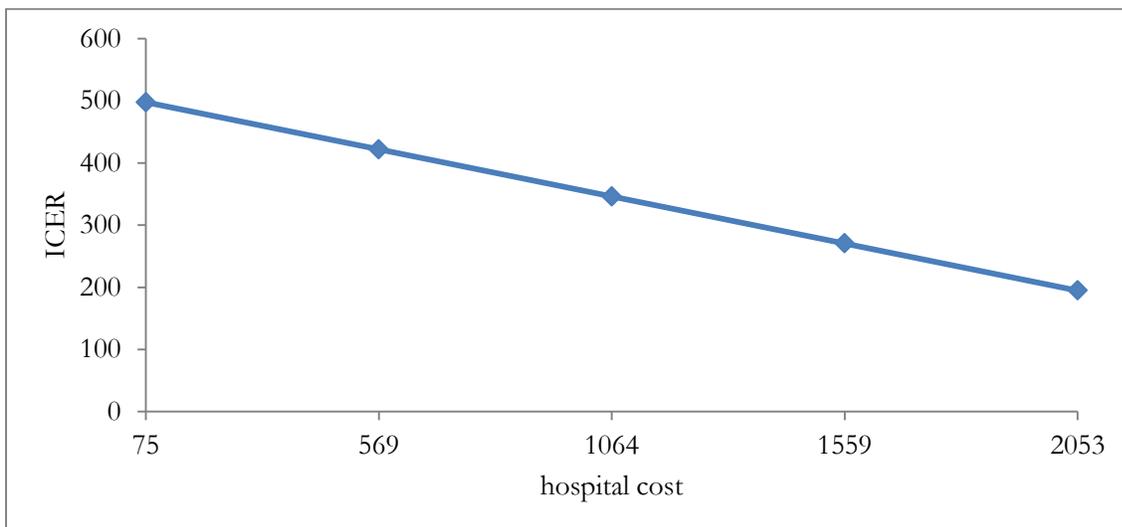

**Table 89: Variable description used in tornado diagram analysis**

Variable	Description
cDeath_Adultsedation	Cost of death in hospital due to RF, adult patients undergoing procedural sedation
cDeath_CPR	Cost of death in hospital due to RF, adult patients undergoing CPR
cDeath_NanSCC	Cost of death in hospital due to RF, neonatal patients in serious or critical condition
clntub	Cost of Intubation
cOD	Cost of treating non-traumatic brain injury (nTBI)
cOxygen	Cost of oxygen supplemental
cPrice_cap	Purchase price of capnography
cRF_hospital_Adultsedation	Hospital cost of respiratory failure, adult patients undergoing procedural sedation
cSupp_cap	Cost of capnography maintenance and consumables
n	Number of patients served per month per device
pEET_corct	Probability ET tube placed correctly
pEET_MisP_nonDetect_cap	ET tube misplacement (not detected; i.e., false negatives), capnography
pEET_MisP_nonDetect_sm	ET tube misplacement (not detected; i.e., false negatives), standard monitoring
pOD	Probability of discharge w/ organ damage
pRE_Adultsedation	Proportion of patients who experience a respiratory events
pRF_Adultsedation_sm	Probability of respiratory failure, adult patients undergoing procedural sedation, standard monitoring
pSAE_cap	Probability of survival of acute event, capnography
pSAE_sm	Probability of survival of acute event, standard monitoring
pSH_cap	Probability of survival to Hospital Discharge, capnography
pSH_sm	Probability of survival to Hospital Discharge, standard monitoring
rCO_Adultsedation_sm	Rate of Supplemental oxygen, adult patients undergoing procedural sedation, standard monitoring
RR_CO_Adultsedation	Relative risk of supplemental oxygen , capnography vs. standard monitoring, adult patients undergoing procedural sedation
RR_RF_Adultsedation	Relative risk of respiratory failure, capnography vs. standard monitoring, adult patients undergoing procedural sedation
RR_Vent_Adultsedation	Relative risk of ventilation assistance, capnography vs. standard monitoring, adult patients undergoing procedural sedation
rVent_Adultsedation_sm	Rate of ventilation assistance, standard monitoring, adult patients undergoing procedural sedation

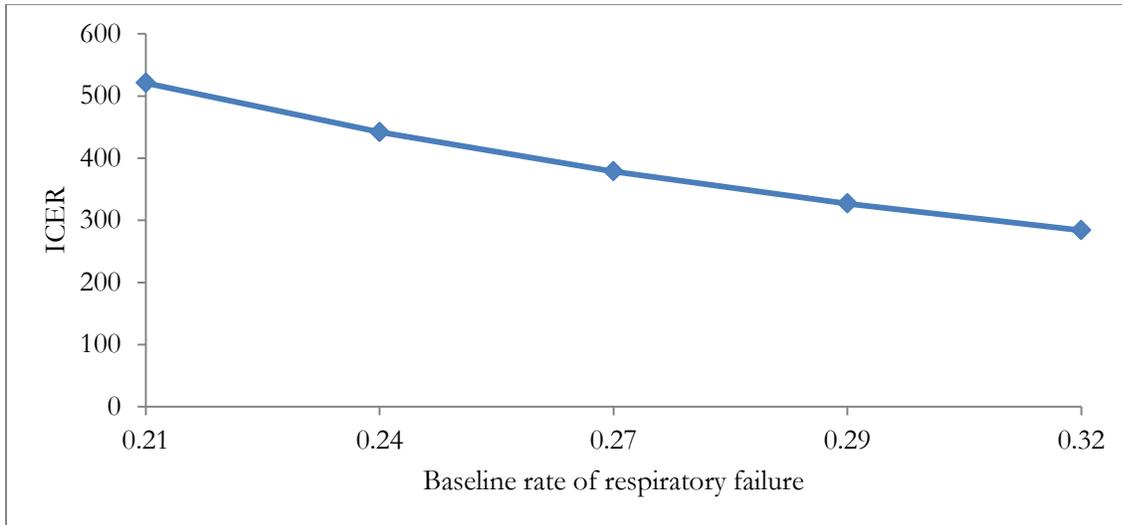

**Figure 14: One-way sensitivity analysis on the impact to the ICER when varying the relative risk of respiratory failure using capnography and standard monitoring compared to standard monitoring alone, adult patients undergoing procedural sedation**

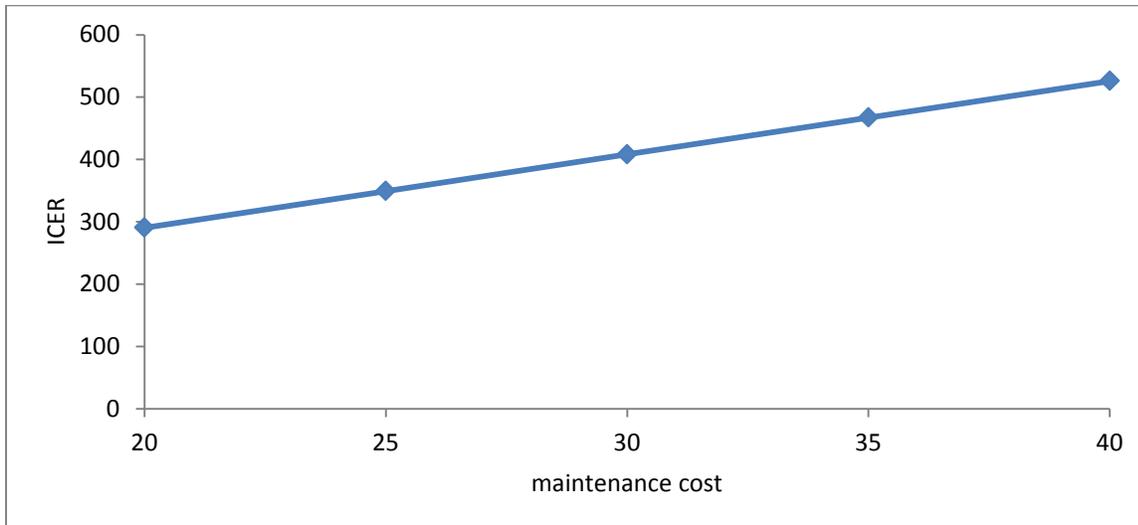

**Figure 15: One-way sensitivity analysis on the impact to the ICER when varying hospital cost for respiratory failure, adult patients undergoing procedural sedation**

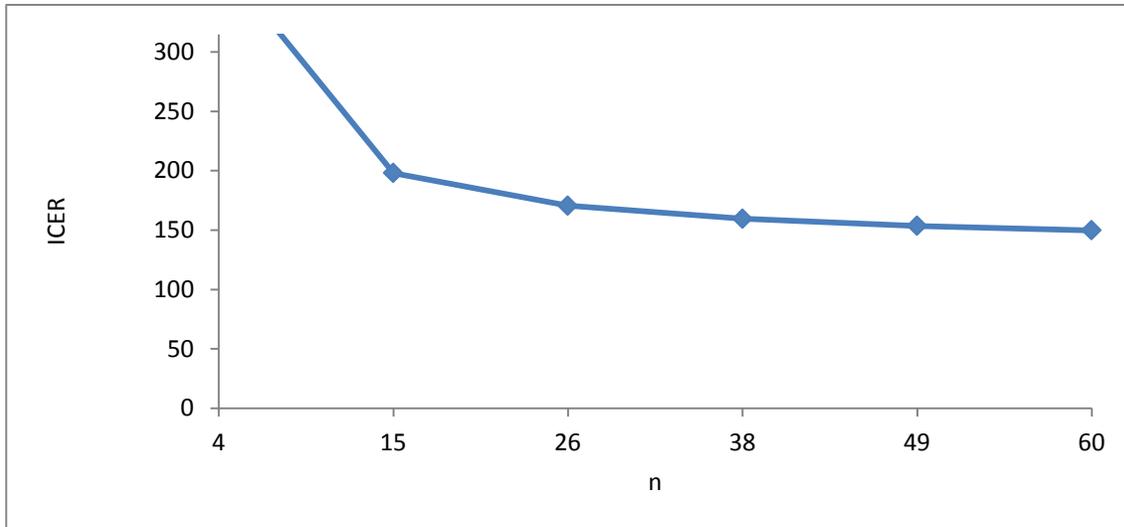

**Figure 16: One-way sensitivity analysis on the impact to the ICER when varying the baseline rate of respiratory failure, adult patients undergoing procedural sedation**

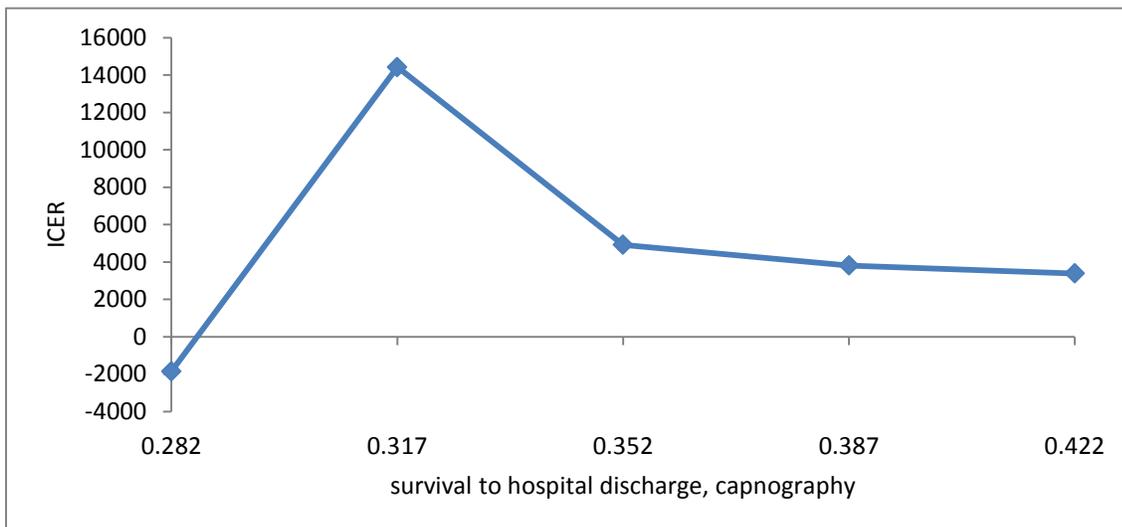

**Figure 17: One-way sensitivity analysis on the impact to the ICER when varying the maintenance cost of the capnography device, adult patients undergoing procedural sedation**

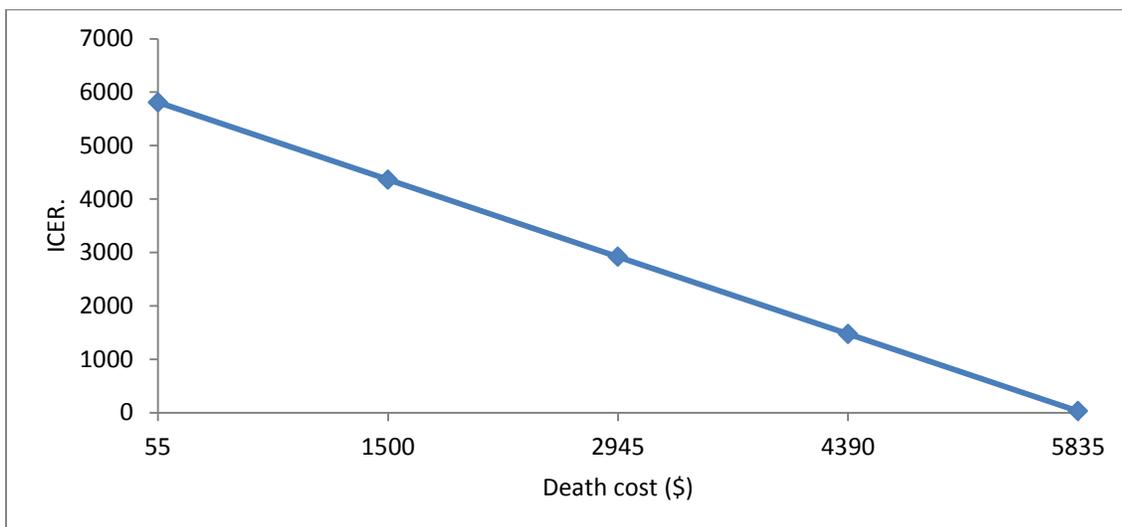

**Figure 21: One-way sensitivity analysis on the impact to the ICER when varying the probability of survival to hospital discharge for patients receiving standard monitoring, adult patients undergoing CPR (primary model). Negative ICERs represent situation in which capnography with standard monitoring is dominated by standard monitoring alone**

**Figure 22: One-way sensitivity analysis on the impact to the ICER when varying the survival probability of acute event for patients receiving standard monitoring, adult patients undergoing CPR (primary model). Negative ICERs represent situation in which capnography with standard monitoring is dominated by standard monitoring alone**

**Figure 23: One-way sensitivity analysis on the impact to the ICER when varying the cost of in-hospital death, adult patients undergoing CPR (primary model). Negative ICERs represent situation in which capnography with standard monitoring is dominated by standard monitoring alone**

**Table 90: Probabilistic results when varying both the baseline rate of respiratory failure and RR of respiratory failure in capnography and standard monitoring compared to standard monitoring alone, ICER (cost per respiratory failure averted)**

RR	Rate		
	0.215	0.268	0.322
<b>Adult patients undergoing procedural sedation</b>			
<b>0.56</b>	349.83	255.36	184.52
<b>0.647</b>	457.43	335.33	246.42
<b>0.733</b>	637.49	463.89	349.45
<b>0.82</b>	963.34	723.13	552.31

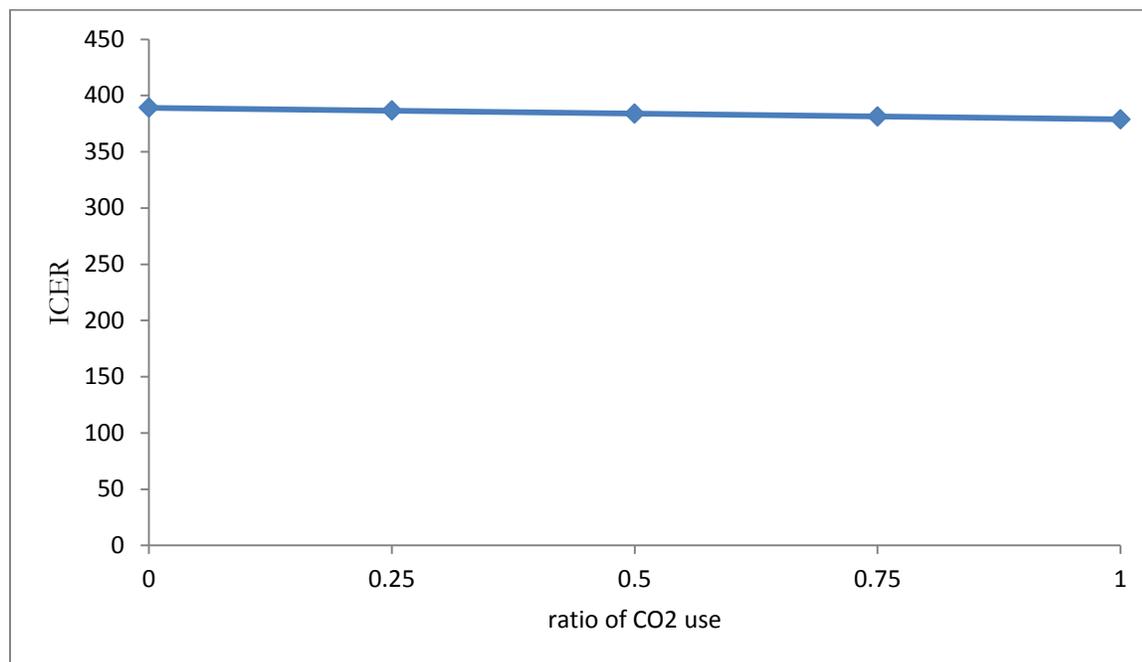

ICER = incremental cost-effectiveness ratio; RR = Relative risk of capnography versus standard monitoring  
Rate: Respiratory failure rate of standard monitoring

**Table 91: Probabilistic results when varying both the number of patients served per month and price of capnography, ICER (cost per respiratory failure averted for sedation group or cost per life saved for CPR group)**

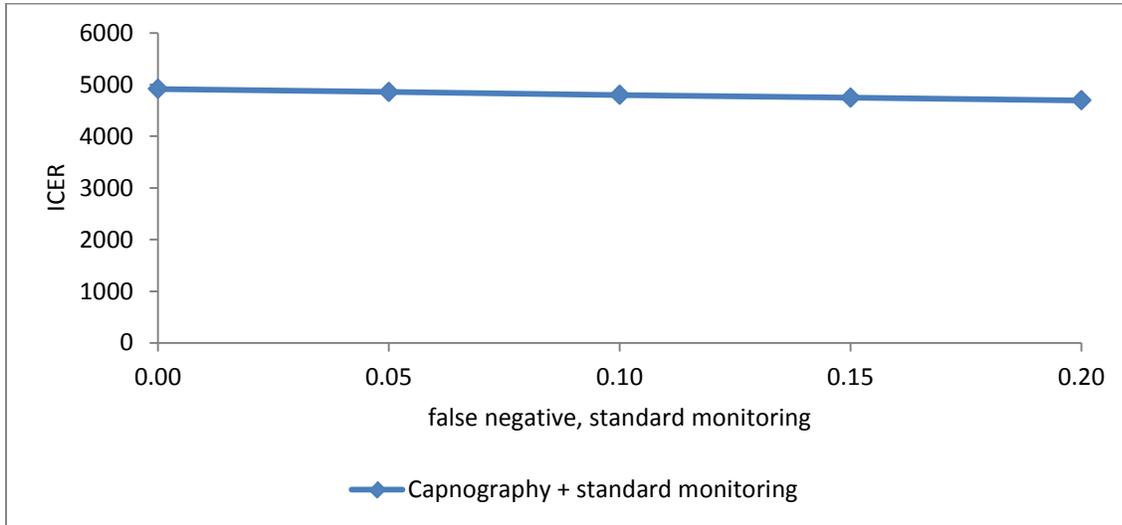

Price (\$)	Number of patients served per month			
	4	23	42	60
<b>Adult patients undergoing procedural sedation</b>				
<b>3000</b>	282.15	158.37	146.51	142.39
<b>5000</b>	374.96	175.56	156.35	148.00
<b>7000</b>	473.06	193.24	165.23	152.55
<b>Adult patients undergoing CPR</b>				
<b>3000</b>	4,585.13	4,103.52	4,099.98	4,069.52
<b>5000</b>	4,904.53	4,204.62	4,141.93	4,094.24
<b>7000</b>	5,279.59	4,207.87	4,150.71	4,112.67

ICER = incremental cost-effectiveness ratio; CPR = cardiopulmonary respiration

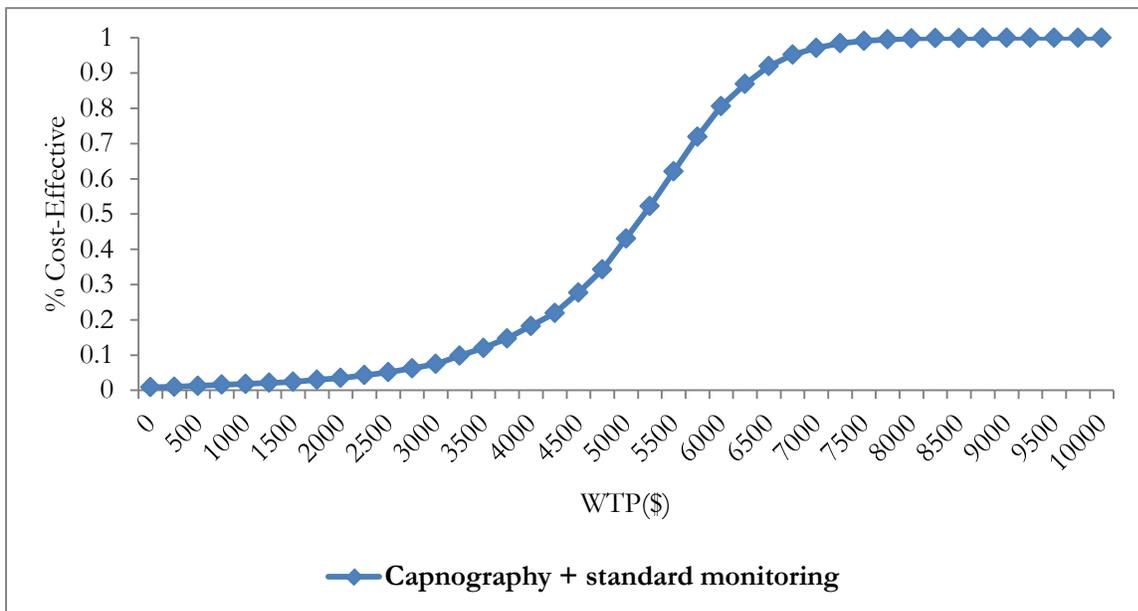

**Figure 24: Structural sensitivity analysis to evaluate the relationship between ventilation assistance and supplemental oxygen use. This figure highlights the extent to which the ICER is impacted when varying the ratio of CO<sub>2</sub> use, adult patients undergoing procedural sedation**

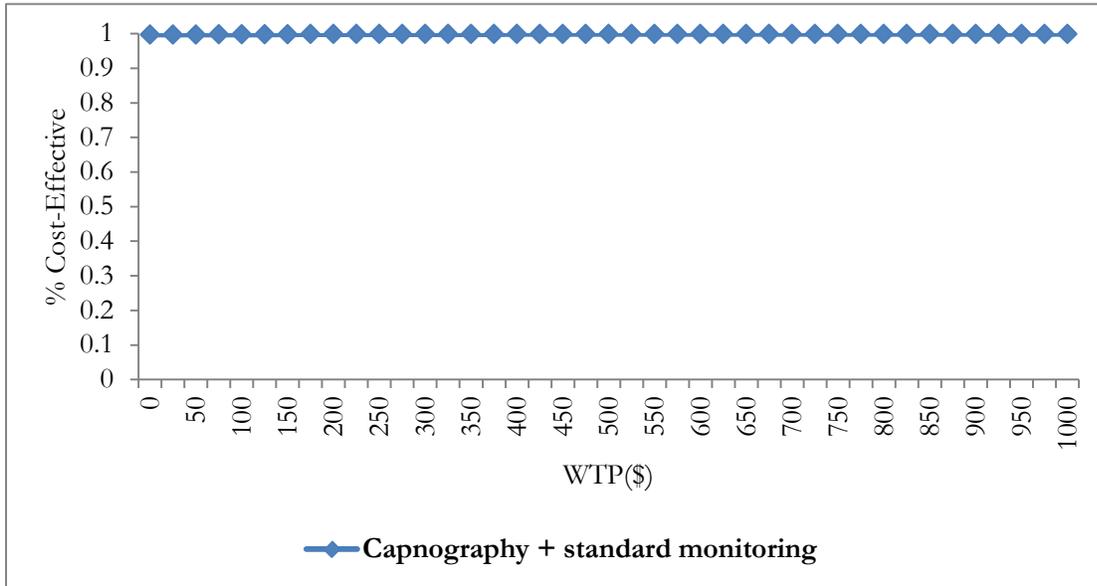

**Figure 25: Structural sensitivity analysis varying the probability of undetected ETT misplacement in patients receiving standard monitoring, adult patients undergoing CPR**

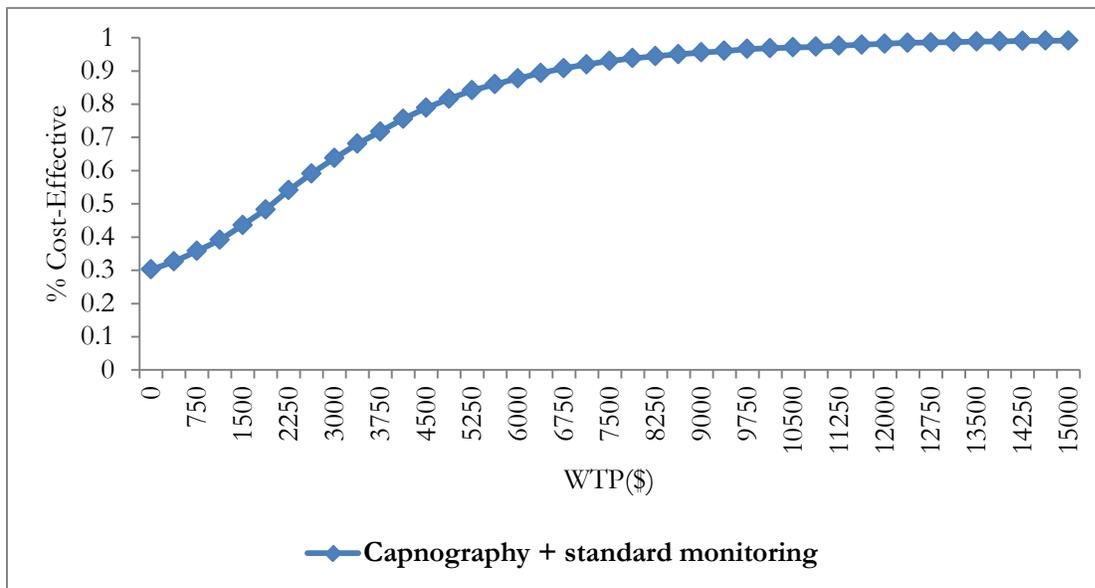

**Figure 26: Cost-effectiveness acceptability curve of capnography with standard monitoring, adult patients undergoing CPR (secondary analysis –using data from Phelan et al<sup>79</sup>)**

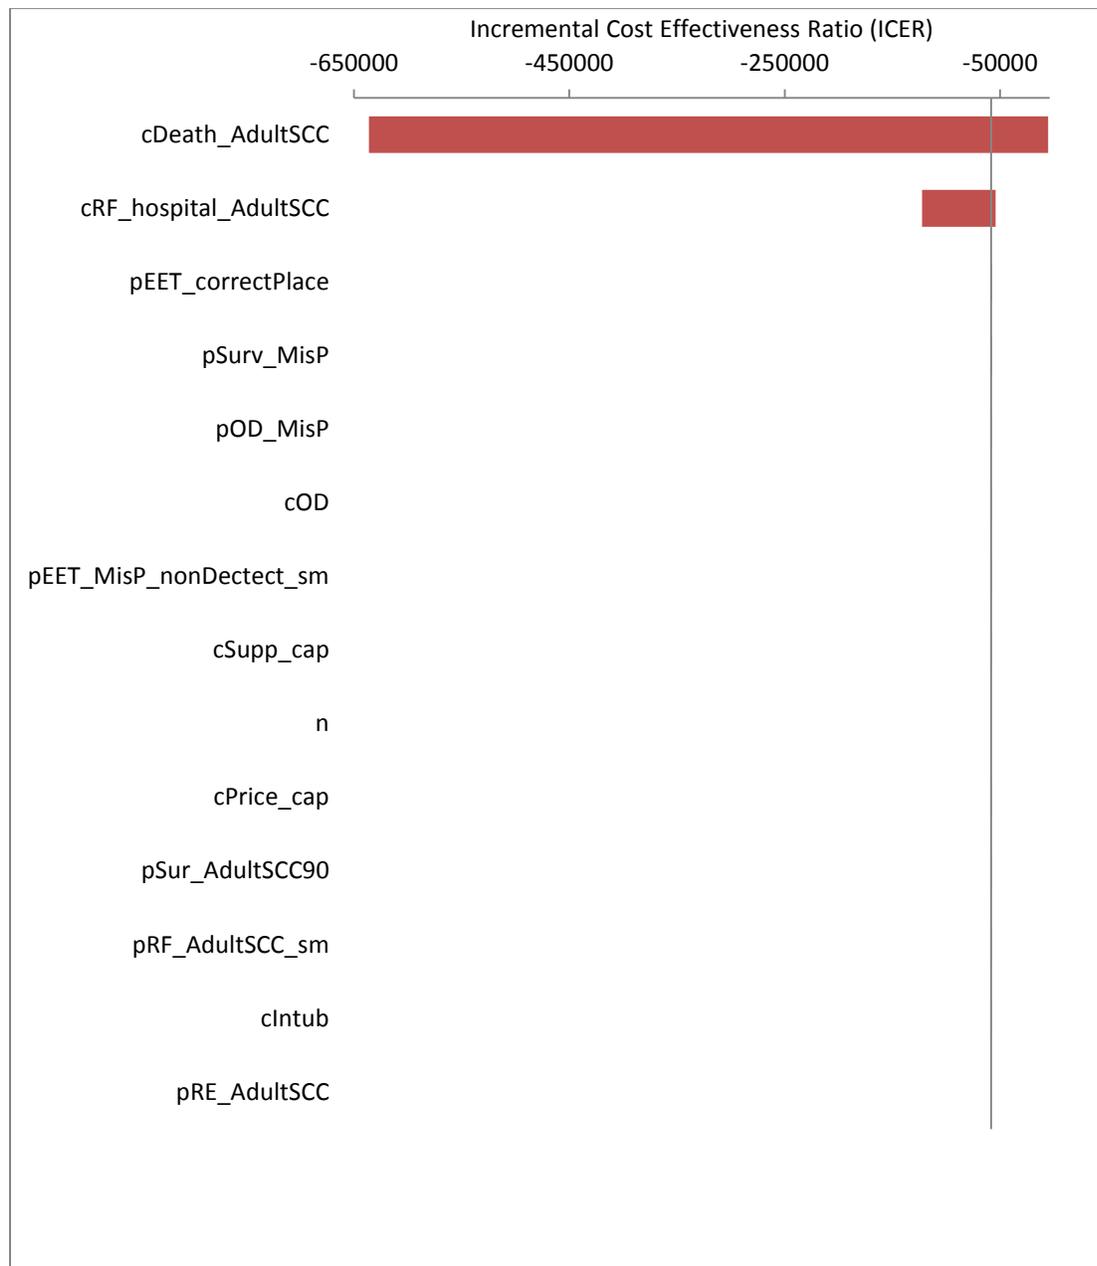

**Figure 27: Cost-effectiveness acceptability curve of capnography with standard monitoring, adult patients in serious or critical condition (exploratory analysis)**

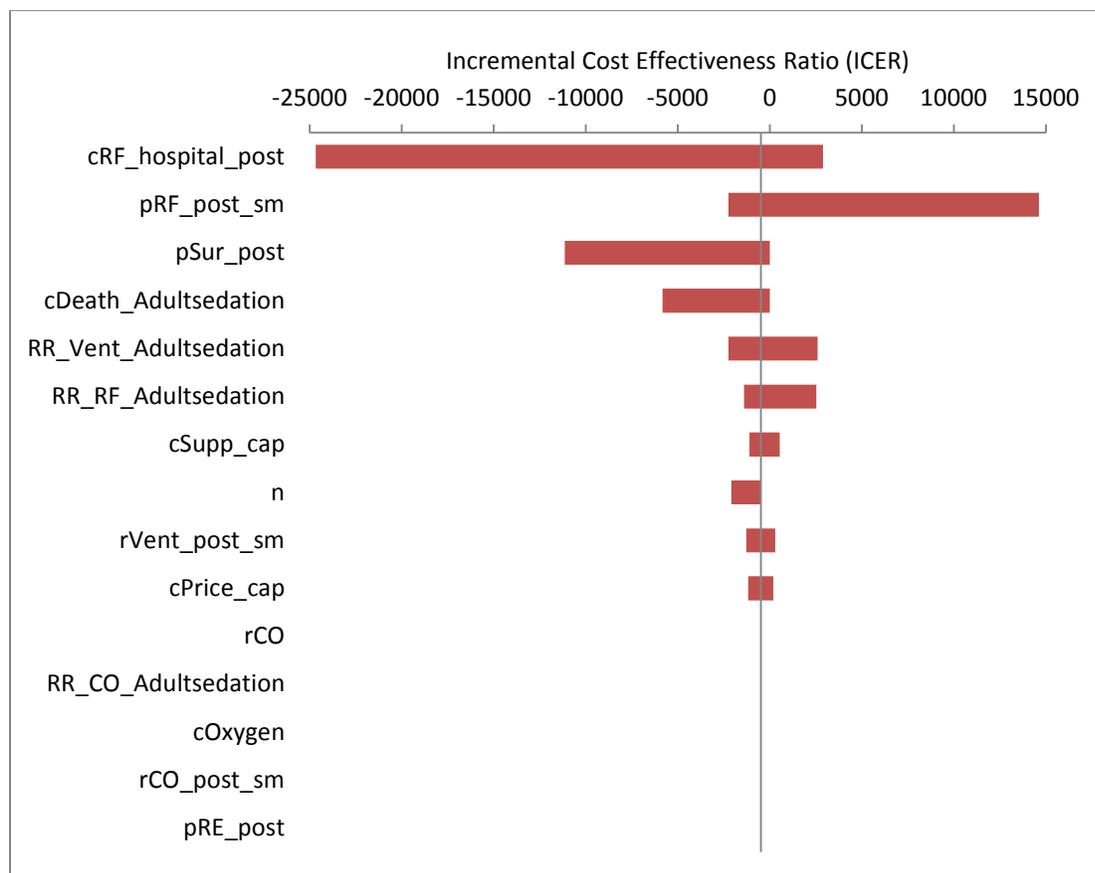

**Figure 28: Cost-effectiveness acceptability curve of capnography with standard monitoring, adult patients in post-operative care (exploratory analysis)**

**Figure 29: Tornado diagram, adult patients in serious and critical condition. Negative ICERs represent situation in which standard monitoring is dominated by capnography. See Table 89 in Appendix M for a description of variables.**

**Figure 30: Tornado diagram, adults in post-operative care. Negative ICERs represent situation in which standard monitoring is dominated by capnography. See Table 89 in Appendix M for a description of variables.**

**Table 92: Results when varying both the number of patients served per month and price of capnography, costs difference (i.e., capnography with standard monitoring – standard monitoring)**

Price (\$)	Number of patients served per month			
	4	23	42	60
<b>Pediatric patients undergoing procedural sedation</b>				
3000	40.00	29.69	28.71	28.33
5000	53.33	31.07	29.41	29.22
7000	56.66	32.64	30.26	29.44
