**About CADTH:** CADTH is an independent, not-for-profit organization responsible for providing Canada's health care decision-makers with objective evidence to help make informed decisions about the optimal use of drugs, medical devices, diagnostics, and procedures in our health care system.

**Funding:** CADTH receives funding from Canada's federal, provincial, and territorial governments, with the exception of Quebec.

## Context and Policy Issues

The Canadian Cancer Society estimates that breast cancer will account for 25.5% of new cancer cases for women in 2017, making breast cancer the leading cancer in Canadian women.<sup>1</sup> Various gene expression tests have been developed to aid treatment planning in early-stage breast cancer. Commercially available gene expression tests include EndoPredict (Myriad Genetics), Oncotype DX (Genomic Health), MammaPrint (Agendia), Mammostrat (Clariant Diagnostic Services) and Prosigna (NanoString). The assays are prognostic and aim to address similar outcomes pertaining to cancer recurrence. The gene expression tests help to differentiate patients that would likely benefit from chemotherapy thus, avoiding overtreatment.<sup>2-4</sup> The tests differ greatly in terms of the platforms used for assessing gene expression as well as the type and quantity of genes tested.<sup>2-4</sup>

EndoPredict assesses 11 genes (including three control genes) and predicts the risk of distant recurrence by categorizing patients as low or high risk.<sup>2,4</sup> MammaPrint determines the risk of recurrence through the assessment of 70 genes. Recurrence is categorized as low or high risk.<sup>4,5</sup> Prosigna (formally known as the PAM50 test) assesses 50 genes (plus five controls) to detect breast cancer subtypes and calculate a 10-year risk of recurrence score.<sup>4</sup> Mammostrat assess five genes to derive a risk score that is typically categorized as high, moderate, or low risk.<sup>5</sup> Oncotype DX is the most studied and widely used breast cancer gene expression test.<sup>2-6</sup> This assay examines 21 genes (including 5 controls) from breast cancer tumor samples and produces a recurrence score (RS) from zero to 100.<sup>4</sup> Patients are classified into 3 categories based on their RS for low, intermediate, or high risk of recurrence. A low RS predicts little benefit from chemotherapy.<sup>4</sup> A 2014 CADTH report<sup>7</sup> examining Oncotype DX found that test results have an impact on approximately 30% of treatment plans for patients with ER-positive, HER2-negative, lymph node negative early stage breast cancer, primarily resulting in lower rates of adjuvant chemotherapy when a low risk score is observed. However changes in patient clinical outcomes resulting from changes in treatment plans were unclear.<sup>7</sup>

While each gene expression test has been independently clinically validated using prospective or retrospective evidence, currently, there is no gold-standard for breast cancer gene expression tests. This highlights the need for comparative assessments of clinical utility and cost-effectiveness.<sup>4,5</sup>

## Research Questions

1. What is the comparative clinical utility of gene expression tests to either predict adjunct chemotherapy or evaluate cancer recurrence risk in women with early stage breast cancer?
2. What is the comparative cost-effectiveness of gene expression tests to either predict adjunct chemotherapy or evaluate cancer recurrence risk in women with early stage breast cancer?

## Key Findings

One moderate quality comparative clinical study provided evidence to suggest that Oncotype DX and EndoPredict were both prognostic for the risk of distant recurrence in the

years zero through five. In years five through 10 EndoPredict was better able to predict distant recurrence compared to Oncotype DX. In comparisons between the high/non-low and the low risk groups, the hazard ratio was higher for EndoPredict.

One moderate quality comparative cost-effectiveness study determined that the use of Mammostrat was more cost-effective and was associated with a cost savings of \$2,268 per patient compared to Oncotype DX.

## Methods

### Literature Search Methods

A limited literature search was conducted on key resources including Ovid Medline, PubMed, The Cochrane Library, University of York Centre for Reviews and Dissemination (CRD) databases, Canadian and major international health technology agencies, as well as a focused Internet search. No methodological filters were applied to limit retrieval by publication type from January 1, 2014 to September 12, 2017. An additional search was done to retrieve economic studies published since January 1, 2012. The search was limited to English language documents.

Rapid Response reports are organized so that the evidence for each research question is presented separately.

### Selection Criteria and Methods

One reviewer screened citations and selected studies. In the first level of screening, titles and abstracts were reviewed and potentially relevant articles were retrieved and assessed for inclusion. The final selection of full-text articles was based on the inclusion criteria presented in Table 1.

**Table 1: Selection Criteria**

<b>Population</b>	Women with early stage, human epidermal growth factor receptor 2 [HER2] negative, lymph node negative, estrogen-receptor [ER] positive and/or progesterone receptor [PR] positive breast cancer
<b>Intervention</b>	Gene expression/profiling tests: <ul style="list-style-type: none"> <li>• Oncotype DX (by Genomic Health)</li> <li>• EndoPredict (by Myriad Genetics)</li> <li>• MammaPrint (by Agendia)</li> <li>• Prosigna (by NanoString)</li> <li>• Mammostrat (by Clariant Diagnostic Services)</li> </ul>
<b>Comparator</b>	Q1-2: Gene expression/profiling tests: <ul style="list-style-type: none"> <li>• Oncotype DX (by Genomic Health)</li> <li>• EndoPredict (by Myriad Genetics)</li> <li>• MammaPrint (by Agendia)</li> <li>• Prosigna (by NanoString)</li> <li>• Mammostrat (by Clariant Diagnostic Services)</li> </ul>

<b>Outcomes</b>	Q1: Clinical utility (predicting who should receive adjunct chemotherapy and/or evaluate cancer recurrence) Q2: Cost-effectiveness
<b>Study Designs</b>	Health technology assessments (HTA), systematic reviews (SR), meta-analyses (MA), randomized control trials (RCT), non-RCTs, and economic evaluations

## Exclusion Criteria

Articles were excluded if they did not meet the selection criteria outlined in Table 1, they were duplicate publications, or were published prior to January 1, 2014 for clinical studies, or January 1, 2012 for economic studies.

## Critical Appraisal of Individual Studies

The included clinical, non-randomized study were critically appraised using the Downs and Black Checklist,<sup>8</sup> and the economic study was assessed using the Drummond checklist.<sup>9</sup> Summary scores were not calculated for the included studies; rather, a review of the strengths and limitations of each included study were described narratively.

## Summary of Evidence

### Quantity of Research Available

A total of 452 citations were identified in the literature search. Following screening of titles and abstracts, 425 citations were excluded and 27 potentially relevant reports from the electronic search were retrieved for full-text review. Twenty-five potentially relevant publications were retrieved from the grey literature search. Of these potentially relevant articles, 50 publications were excluded for various reasons, while two publications met the inclusion criteria and were included in this report. Appendix 1 describes the PRISMA flowchart of the study selection.

Additional references of potential interest are provided in Appendix 5. These publications did not meet the inclusion study for this Rapid Response.

### Summary of Study Characteristics

The details of the individual study characteristics for the included publications are provided in Appendix 2.

#### *Study Design, Country of Origin, and Patient Population*

Buus et al. published a clinical study based on data and RNA samples from the translational sub-study of the Arimidex, Tamoxifen, Alone or in combination trial (transATAC).<sup>2</sup> This previously conducted translational RCT was designed to test the effectiveness of two endocrine therapies in post-menopausal women with hormone receptor-positive, HER2-negative, chemotherapy-naïve breast cancer. Patients were recruited from the United Kingdom (UK) and required to have an Oncotype DX recurrence score (RS) and at least 350 ng residual RNA available from the transATAC study to be used for the EndoPredict (EP) assay.

Mislick et al. published a cost-effectiveness study for the comparison of Mammostrat and Oncotype DX using a US third-party payer perspective.<sup>10</sup> A 10-year Markov model was developed using model inputs derived from the National Surgical Adjuvant Breast and Bowel Project (NSABP). The NSABP collected data from women with node-negative, ER-positive, early stage breast cancer.<sup>10</sup> The NSABP did not collect all types of data required for the cost-effectiveness study so assumptions were required for certain aspects of the model (i.e. proportion of women at each risk level who received chemotherapy). Mislick et al. used one set of values for the base-case analysis and conducted several sensitivity analyses to account for uncertainty.

### *Interventions and Comparators*

Buus et al. compared the recurrence score (RS) from Oncotype DX with the EndoPredict (EP) and an alternative EndoPredict score (EPclin).<sup>2</sup> EPclin combined the score from the original EndoPredict with clinical information on tumor size and nodal status.

The cost-effectiveness study by Mislick et al. compared the tumor subtyping assays Mammostrat and Oncotype DX.<sup>10</sup> Model cost inputs included the cost of chemotherapy, the cost of Mammostrat and Oncotype DX, the cost of cancer recurrence, death due to chemotherapy cost, minor and severe chemotherapy adverse event cost, discount rate, and end of life costs.

### *Outcomes*

The clinical study by Buus et al. assessed the prognostic value of the recurrence score from Oncotype DX (low/non-low), the EndoPredict (low/high risk) score, and the alternative EndoPredict (low/high) score for the assessment of distant recurrence risk.<sup>2</sup> Distant recurrence was assessed in the period of zero to 10 years, as well as zero to five years, and five to 10 years.

The cost-effectiveness study by Mislick et al. aimed to assess the cost-effectiveness for the use of Mammostrat compared to Oncotype DX to inform the treatment of breast cancer using real and simulated data.<sup>10</sup> The cost-effectiveness was reported as base-case costs and quality-adjusted life years.

### **Summary of Critical Appraisal**

The details of the critical appraisal for the included publications are provided in Appendix 3.

The clinical study by Buus et al. used data and RNA samples from transATAC.<sup>2</sup> The aim, patient characteristics, main outcomes, and interventions of the Buus et al. study were clearly described. The results were reported for various sub-groups including a lymph node-negative group. Analysis was appropriately conducted and represented with 95% confidence intervals and actual probability values. The relevant sub-group (node-negative patients) accounted for 73.3% of the patient population. It is unclear if the main study or the node-negative sub-group analysis was sufficiently powered as the authors did not report power calculations. While the authors state that patients undergoing combination therapy were excluded from the analysis, it is unclear if the single therapy (arimidex or tamoxifen) examined in the original transATAC study is relevant to the main outcome (distant recurrence) as the authors did not include therapy-related sub-group analysis. The internal validity of the study was preserved through blinding of the analysts to clinical data. It was unclear if selection bias was present as the study required a minimum of 350 ng residual RNA for inclusion in the study. The authors did not provide an explanation for why some

samples had insufficient RNA samples after the original transATAC study. The external validity was limited to the UK population and to women treated with arimidex or tamoxifen for five years. It is unclear if this treatment is comparable to treatment received in Canada for women with clinically similar cases.

The cost-effectiveness study by Mislick et al. used clear and relevant methodology and was generally well conducted.<sup>10</sup> The research question, rationale and economic importance of the study were clearly stated. The model inputs and data sources were clearly described. The authors highlighted specific areas where real data was missing and simulated data based on assumptions were used. The data used in the study were derived from the NSABP. The clinical data from the NSABP was used in the development and validation of Mammostrat and Oncotype DX, and was thus determined to be an appropriate sample. The NSABP did not have data for the model parameters for the proportion of women at each risk level who received chemotherapy, thus the model relied on assumptions where the patients who were high, medium, and low risk were assumed to use chemotherapy at the following proportions: 0.8, 0.5 and 0.1, respectively. It was unclear if these assumptions about proportions were guided by the literature or if they would be applicable to a Canadian population. The base population for the analysis was not identical between the two test groups, as 20% to 30% of the samples were depleted in the initial assessment of Oncotype DX and were subsequently unavailable for the assessment with Mammostrat. To counter this limitation, the authors made statistical adjustments to make the study populations equivalent. Several relevant sensitivity analyses were conducted to assess the impact of changing model parameters. Finally, the model was based on a US third-party payer perspective, which inherently limits the external validity to the US population and reduces the applicability to the Canadian population.

## Summary of Findings

*What is the comparative clinical utility of gene expression tests to either predict adjunct chemotherapy or evaluate cancer recurrence risk in women with early stage breast cancer?*

Oncotype DX RS and the two versions of Endopredict (EP and EPclin) were each similarly prognostic for the risk of distant recurrence in the years zero through five (likelihood ratio [LR] chi-square: EP=15.5; LR chi-square: EPclin= 17.0; LR chi-square: RS = 18.7).<sup>2</sup> In the years five to 10, RS was less likely to predict distant recurrence compared to the EP and EPclin (LR chi-square: EP = 22.7; LR chi-square: EPclin = 15.5; LR chi-square: RS = 4.8). In this analysis the LR test was based on Cox proportional hazard models and indicates an increase in risk of distant recurrence associated with an increase in each assay's score. In comparisons between the high/non-low and the low risk groups, the hazard ratio was similar for RS and EPclin at 3.72 (95% confidence interval [CI]: 2.17 to 6.39) and 3.90 (95% CI: 2.33 to 6.52), respectively. The hazard ratio was the highest for EP at 5.15 (95%CI: 2.44 to 10.85), indicating the greatest increase in the risk of recurrence with the high risk EP group versus low risk EP group compared to Oncotype DX RS and EPclin.

*What is the comparative cost-effectiveness of gene expression tests to either predict adjunct chemotherapy or evaluate cancer recurrence risk in women with early stage breast cancer?*

In a comparison of Mammostrat and Oncotype DX in a clinically similar population, Mammostrat was determined to be more cost-effective with a cost savings of \$2,268 per patient.<sup>10</sup> This study determined that both assays resulted in similar life years (9.880 and 9.882) and quality-adjusted life years (7.935 and 7.940) for Mammostrat and Oncotype DX,

respectively. Sensitivity analyses based on alternative assumptions for chemotherapy cost, recurrence cost, mild and severe adverse event cost, and altering the recurrence-free proportion parameter showed a high degree of consistency with the main results with Mammostrat remaining cost-effective over Oncotype DX.

### Limitations

The clinical study by Buus et al. was inherently limited as it used data from a previously conducted RCT that was designed to address a different research question.<sup>2</sup> Thus, it was unclear if the sub-group analysis for node-negative patients was sufficiently powered. The external validity of this study was limited to the UK population; patients were treated with either treated with arimidex or tamoxifen for 5 years and it is unclear if this is comparable to the treatment Canadian women receive, or if use of the different treatments influenced the results.

The cost-effectiveness study was limited by assumptions on the proportion of women at each risk level who received chemotherapy in the 10-year model.<sup>10</sup> It is unclear if these assumptions were based on evidence. Additionally, the model was based on a US third-party payer perspective, which inherently limits the external validity from the perspective of the Canadian population as costs associated with treatment were likely not equivalent.

### Conclusions and Implications for Decision or Policy Making

The single comparative clinical utility study identified in this Rapid Response report evaluated the breast cancer assays Oncotype DX and EndoPredict.<sup>2</sup> This study examined the prognostic value of both assays and determined that they provided a similar amount of prognostic information for distant recurrences occurring in the first five years. EndoPredict provided more prognostic information for distant recurrences occurring from five to ten years later. The hazard ratio for low versus high EndoPredict score was higher compared to low versus non-low Oncotype DX recurrence score. Overall, these results indicate that both Oncotype DX and EndoPredict are potentially useful assays in determining the risk of distant recurrence.

The single cost-effectiveness study identified in this Rapid Response evaluated the breast cancer assays Oncotype DX and MammaPrint.<sup>10</sup> Using a combination of real and simulated data, this study determined that Mammostrat was more cost-effective with a cost savings of \$2,268 per patient using a US third-party payer perspective.<sup>10</sup> In sensitivity analyses, varying the cost of chemotherapy, recurrence, and mild and severe adverse events still showed cost savings associated with Mammostrat. Varying the proportions of recurrence-free patients still showed cost savings with Mammostrat.

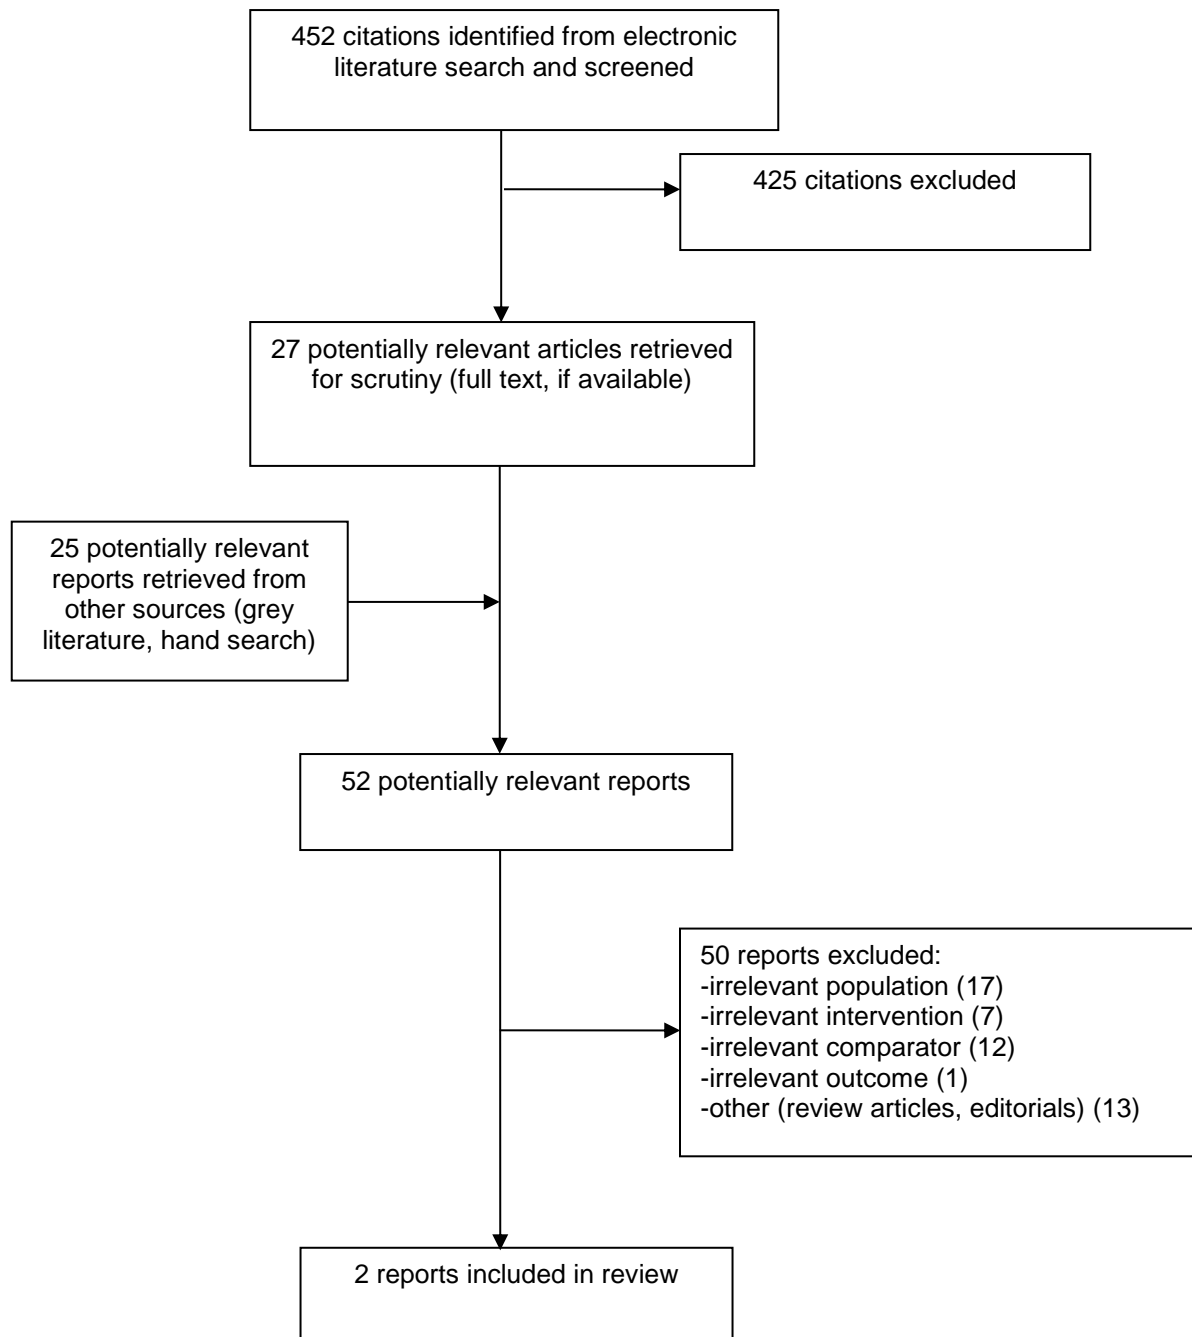

Overall, the findings for the comparative clinical utility and cost-effectiveness are limited by the quantity and scope of studies as one of each type of study was identified. The gene expression assays MammaPrint and Prosignia were not included in either of the studies evaluated in this Rapid Response. The US third-party payer perspective from the cost-effectiveness study limits its external validity to a Canadian population. Further comparative study is warranted.
