<b>SALOME</b>	Study to Assess Long-term Opioid Maintenance Effectiveness

## Key Messages

- Injectable diacetylmorphine might provide more benefits and lower costs compared with oral methadone maintenance therapy in patients with severe opioid use disorder.
- The Canadian Research Initiative in Substance Misuse guideline recommends that both injectable diacetylmorphine and hydromorphone should be considered as treatment options for individuals with severe, treatment-refractory opioid use disorder and ongoing illicit injection opioid use, and that the injectable opioid agonist treatment should have an end date to transition to an oral opioid agonist treatment.
- No recent studies on the clinical effectiveness of diacetylmorphine for injection in comparison with methadone or buprenorphine were identified.
- No cost-effectiveness studies of injectable diacetylmorphine compared with buprenorphine were identified.

## Context and Policy Issues

Opioid dependence has devastating consequences for individuals, families, and society. Between January 2016 and September 2021, 26,690 Canadians died from opioid-related toxicity.<sup>1</sup> In 2021, there were approximately 20 opioid toxicity deaths per day in Canada compared with 7 deaths per day in 2016 and 12 deaths per day in 2018.<sup>1</sup> Almost all (98%) of those deaths were accidental, and 88% of these accidental deaths occurred in British Columbia, Alberta, or Ontario.<sup>1</sup> From January 2016 to September 2021, there were 29,228 hospitalizations due to opioid-related poisoning in Canada and 12,977 hospitalizations due to stimulant-related poisoning.<sup>1</sup> Opioid-related poisoning hospitalizations increased by 27% in the first year of pandemic (April 2020 to March 2021) compared with the previous year (April 2019 to March 2020).<sup>1</sup>

Maintenance therapy with oral opioid agonist treatment medications, such as methadone or buprenorphine, can be effective in decreasing drug use and preventing mortality and illegal activity in many individuals with opioid use disorder.<sup>2</sup> However, a subset of individuals with severe opioid use disorder who used to inject opioids may not benefit from oral maintenance treatment, therefore alternative approaches are needed.<sup>3</sup> In 2009, the North American Opiate Medication Initiative (NAOMI) trial conducted in Canada found that injectable diacetylmorphine (DAM) was more effective than oral methadone maintenance therapy (MMT) for higher retention and response rates in addiction treatment, and reduction in rates of illicit opioid use or illegal activity in long-term users of injectable heroin.<sup>4</sup> However, DAM had more serious adverse events compared with oral MMT.<sup>4</sup> At that time, DAM was not available in Canada.<sup>5</sup> A subsequent trial, the Study to Assess Long-term Opioid Maintenance Effectiveness (SALOME), was designed to find an acceptable alternative to DAM, and showed that injectable hydromorphone (HDM) was noninferior to injectable DAM and had fewer adverse events.<sup>6</sup> Health Canada has recently approved DAM as an injectable opioid agonist therapy for adult patients with severe opioid use disorder who use injectable opioids and have failed previous opioid agonist therapy, including oral MMT.<sup>7</sup> DAM is delivered in a supervised setting due to its risk of serious adverse events, such as overdose and seizure.<sup>4,7</sup> Injectable DAM can be provided in combination with oral MMT to prevent withdrawal symptoms.<sup>7</sup>

This report aims to summarize the evidence on the clinical effectiveness and cost-effectiveness of DAM for injection versus methadone or buprenorphine for adults with

opioid dependence. Additionally, this report also aims to summarize the recommendations from evidence-based guidelines regarding the use of DAM for injection for adults with opioid dependence.

## Research Questions

1. What is the clinical effectiveness of DAM for injection versus methadone or buprenorphine for adults with opioid dependence?
2. What is the cost-effectiveness of DAM for injection versus methadone or buprenorphine for adults with opioid dependence?
3. What are the evidence-based guidelines regarding the use of DAM for injection for adults with opioid dependence?

## Methods

### Literature Search Methods

A limited literature search was conducted by an information specialist on key resources including MEDLINE, Embase, the Cochrane Database of Systematic Reviews, the International HTA Database, the websites of Canadian and major international health technology agencies, as well as a focused internet search. The search strategy comprised both controlled vocabulary, such as the National Library of Medicine's MeSH (Medical Subject Headings), and keywords. The main search concepts were injectable diacetylmorphine and opioid dependence. No filters were applied to limit the retrieval by study type. Conference abstracts were excluded. If possible, retrieval was limited to the human population. The search was completed on June 1, 2022, and limited to English-language documents published since January 1, 2017.

### Selection Criteria and Methods

One reviewer screened citations and selected studies. In the first level of screening, titles and abstracts were reviewed and potentially relevant articles were retrieved and assessed for inclusion. The final selection of full-text articles was based on the inclusion criteria presented in [Table 1](#).

### Exclusion Criteria

Articles were excluded if they did not meet the selection criteria outlined in [Table 1](#) or they were published before 2017. Guidelines with unclear methodology were also excluded.

### Critical Appraisal of Individual Studies

The included publications were critically appraised by 1 reviewer using the following tools as a guide: The Drummond checklist<sup>8</sup> for economic evaluations, and the Appraisal of Guidelines for Research and Evaluation (AGREE) II instrument<sup>9</sup> for guidelines. Summary scores were

not calculated for the included studies; rather, the strengths and limitations of each included publication were described narratively.

## Summary of Evidence

### Quantity of Research Available

A total of 326 citations were identified in the literature search. Following screening of titles and abstracts, 320 citations were excluded and 6 potentially relevant reports from the electronic search were retrieved for full-text review. No potentially relevant publications were retrieved from the grey literature search for full-text review. Of these 6 potentially relevant articles, 4 publications were excluded for various reasons, and 2 publications met the inclusion criteria and were included in this report. These comprised 1 economic evaluation study and 1 evidence-based guideline. The Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA)<sup>10</sup> flow chart of the study selection is presented in [Appendix 1](#).

### Summary of Study Characteristics

Additional details regarding the characteristics of the included economic evaluation study<sup>11</sup> ([Table 2](#)) and evidence-based guideline<sup>12</sup> ([Table 3](#)) are provided in [Appendix 2](#).

### Study Design

The economic evaluation study by Bansback et al. (2018)<sup>11</sup> used an existing semi-Markov cohort model<sup>13</sup> to assess the cost-effectiveness of HDM or DAM compared with oral MMT for treatment of severe opioid use disorder in adults. The clinical data were from the SALOME<sup>6</sup> and NAOMI<sup>4</sup> trials, and data from an 11-year population study of methadone recipients in British Columbia.<sup>14</sup> The SALOME trial<sup>6</sup> found that HDM was noninferior to DAM for all clinical

**Table 1: Selection Criteria**

Criteria	Description
Population	Adults with opioid dependence
Intervention	Diacetylmorphine for injection
Comparator	Q1 and Q2: Methadone or buprenorphine (any formulations, including buprenorphine-naloxone) Q3: Not applicable
Outcomes	Q1: Clinical benefits and harms (e.g., retention in treatment, illicit drug use, overdose rates, mortality, health-related quality of life, social functioning [e.g., attendance at school or work], emotional and psychological functioning [e.g., anxiety, depression, sleep], adverse events) Q2: Cost-effectiveness (e.g., incremental cost per health benefit or QALY gained) Q3: Recommendations regarding best practices (e.g., appropriate patient populations and clinical settings, treatment protocols [e.g., dosing and frequency], recommended safeguards, strategies to mitigate harms, adverse events, and misuse)
Study designs	Health technology assessments, systematic reviews, randomized-controlled trials, non-randomized studies, economic evaluations, evidence-based guidelines

Q = question; QALY = quality-adjusted life-year.

outcomes, with the exception that HDM had lower rates of adverse events compared to DAM. The NAOMI trial<sup>4</sup> found DAM to be superior to oral MMT. A mixed treatment comparison approach was used to compare HDM and DAM with oral MMT. Resource use included utilization of drugs, non-protocol visits to health professionals, and other health care resources (hospitalizations, and criminal involvement and charges). All costs were calculated by multiplying resource use by respective costs, adjusted to 2015 Canadian dollars, and discounted at 5% per year. Health-related quality of life (HRQoL) was incorporated in terms of utility values on a scale from 0 (death) to 1 (full health), combined with life-years to generate quality-adjusted life-years (QALYs), which was discounted at 5%. The analyses were conducted from a Canadian societal perspective over a 50-year life-time horizon. A series of scenario analyses including the Ministry of Health perspective were conducted to explore the sensitivity of the results to specific parameter uncertainty, alternative assumptions, and sources of data.

The included evidence-based guideline<sup>12</sup> was developed by the Canadian Research Initiative in Substance Misuse (CRISM), which provides recommendations on defining the patient population considered for injectable opioid agonist treatment and outlining considerations for medication selection and length of treatment. A systematic search of the literature was conducted, and the quality of evidence and the strength of recommendations were assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

## Country of Origin

The economic evaluation study<sup>11</sup> and the guideline<sup>12</sup> was conducted by authors from Canada.

## Patient Population

Patients considered in the economic evaluation study<sup>11</sup> were from the cohorts of adults with severe opioid use disorder from the SALOME trial<sup>6</sup> and the NAOMI trial.<sup>4</sup> In the SALOME trial,<sup>6</sup> patients had mean age of 44 years, 70% were men and 30% were women, and the average duration of usage was described as “15 years of injecting street heroin.” In the NAOMI trial,<sup>4</sup> patients had mean age of 40 years, 61% were men and 39% were women, and the average duration of usage was 17 years of injection-drug use.

The target population of the CRISM guideline<sup>12</sup> is adults with severe opioid use disorder, while the intended users are Canadian health professionals with clinical recommendations and guidance for the treatment of severe opioid use disorder with injectable opioid agonist treatment.

## Interventions and Comparators

HDM was compared with DAM using within-trial analysis from the SALOME study,<sup>6</sup> and HDM was indirectly compared with oral MMT using DAM as a common comparator from the NAOMI trial.<sup>4</sup>

The CRISM guideline<sup>12</sup> formulated its recommendations concerning the injectable opioid agonist treatment (i.e., DAM or HDM).

## Outcomes

The outcomes in the economic evaluation study<sup>11</sup> were incremental costs, QALYs, and incremental cost-effectiveness ratio (ICER), which was calculated as the incremental cost per QALY change.

Major outcomes considered in the CRISM guideline<sup>12</sup> were high retention rates, reduction of street opioid use, and adverse events.

## Summary of Critical Appraisal

Additional details regarding the strengths and limitations of included publications are provided in [Appendix 3 \(Table 4\)](#).

The economic evaluation study by Bansback et al. (2018)<sup>11</sup> clearly stated the objective, the economic importance of the research question, the rationale for choosing the alternative comparators (i.e., DAM versus oral MMT, HDM versus oral MMT, and HDM versus DAM), and the type of economic evaluation (i.e., cost-effectiveness analysis) that was conducted. An existing semi-Markov cohort model for the purposes of the life-time analysis was further developed with a societal perspective. For data collection, the study clearly stated the source of effectiveness estimates with details of the design and findings (i.e., from 2 clinical trials, and data from an 11-year population study of methadone recipients in British Columbia), and the resource use and costs. The study clearly stated the outcome measures for economic evaluation (i.e., incremental costs, QALYs, and ICER). A Markov model was presented with all parameters used in the analysis. For the analysis and interpretation of results, the study clearly stated the time horizon of costs and benefits, statistical tests and confidence intervals, justification for the choice of variables for sensitivity analysis, and the ranges over which the variables were varied. A 5% discounting rate was applied for all costs and QALYs with a 50-year life-time horizon. The study reported incremental analysis and presented major outcomes in a disaggregated as well as aggregated form. Probabilistic analysis was used to estimate the means and 95% confidence intervals (CIs) of total costs, QALYs, and ICERs to reflect parameter uncertainty. The conclusion in the study was based on the data reported and was accompanied by the appropriate caveats. Overall, the study was of good methodological quality with respect to the study design, data collection, and analysis and interpretation of results.

The CRISM guideline<sup>12</sup> was explicit in terms of scope and purpose (i.e., objectives, health questions, and populations), and had clear presentation (i.e., specific and unambiguous recommendations, different options for management of the condition or health issue, and easy to find key recommendations). In terms of stakeholder involvement, the guidelines clearly defined target users and the development groups. The views and preferences of the target population (e.g., patients, public) were sought. For rigour of development, the guideline reported systematic methods used to search for evidence, criteria for selecting evidence, explicit links between recommendations and the supporting evidence, and methods of formulating the recommendations. The guideline considered health benefits, side effects, and risks in formulating the recommendations, and it was externally peer-reviewed before publication. The guideline assessed the quality of evidence and graded the level of recommendations using the GRADE tool. For clarity, the recommendations in the guideline are specific and unambiguous, provide different options for management of the condition, and are easily identifiable. For applicability, the guideline was explicit in terms of facilitators and barriers to application, advice on how the recommendations can be put into practice, and resource implications (e.g., considering costs in recommendations). For editorial independence, the guideline reported competing interests of the guideline development group members and that the views of the funding body did not have influence on the content of the guidelines. Overall, the guideline was of good methodological quality.

## Summary of Findings

The main study findings and authors' conclusions are presented in [Appendix 4](#).

### Clinical Effectiveness of DAM for Injection for Adults With Opioid Dependence

No clinical studies comparing the clinical effectiveness of DAM for injection versus methadone or buprenorphine for adults with opioid dependence were identified; therefore, no summary can be provided.

### Cost-Effectiveness of DAM for Injection for Adults With Opioid Dependence

Because the comparisons of HDM with DAM and HDM with oral MMT were not in scope in this review, only the cost-effectiveness results of DAM compared with oral MMT are presented here. Results for the comparisons of HDM with DAM and HDM with oral MMT are presented in [Table 6](#) of [Appendix 4](#).

The model results suggested that injectable DAM provided 3.5 additional years of life compared with oral MMT (18.4 years versus 14.9 years). When combining life-years with quality of life, the injectable DAM strategy provided a greater benefit in comparison to the oral MMT strategy (8.4 QALYs versus 7.4 QALYs; difference = 1.0 QALY). For total costs, DAM was less expensive compared with oral MMT (\$1.01 million versus \$1.15 million; difference = -\$0.14 million) during the life-time. More than 90% of the cost was attributable to involvement in property and violent crime, and less than 3% attributable to treatment. The DAM strategy had a decrease in criminal charges for property crime per person-year of 0.5 compared with MMT and had 5.4 fewer involvements with property crimes per person-year (9.6 versus 15.0). Therefore, injectable DAM was considered to dominate oral MMT (ICER = dominates; 95% CI, dominates to 306.8) due to more benefit and less cost. Probabilistic analysis showed that injectable DAM had a 75% probability of dominating oral MMT. The results were consistent with all scenarios, with the exception of the Ministry of Health perspective.

### Guidelines

The CRISM guideline<sup>12</sup> provided 3 key recommendations based on the existing literature on injectable opioid agonist treatment. First, the guideline recommends that injectable opioid agonist treatment should be considered for individuals with severe, treatment-refractory opioid use disorder and ongoing illicit injection opioid use. This recommendation was rated conditional based on moderate quality of evidence. Second, the guideline suggests that both DAM and HDM are acceptable treatment options for individuals who are likely to benefit from injectable opioid agonist treatment. This recommendation was considered strong despite low quality of evidence, based on expert consensus, clinical experience in British Columbia, low risk of adverse events of HDM compared with DAM, and the unavailability of prescribed DAM in Canada at that time. Third, the guideline recommends that injectable opioid agonist treatment should be provided as an open-ended treatment, with decisions to transition to oral opioid agonist treatment. This recommendation was considered strong despite low quality of evidence based on the risk of fentanyl-contaminated illicit opioid use and WHO's recommendation for opioid agonist treatment as an open-ended treatment.

### Limitations

The economic evaluation study<sup>11</sup> had several limitations. First, not all data were able to capture costs related to possession or dealing of drugs, disorderly conduct, sex work, driving violations, or illegal activities. Including these costs may further improve the cost-savings from treatment with DAM or HDM. Second, the study made several assumptions

for transitions between treatment states that were beyond the trial data. However, various scenario analyses found that all were insensitive to the assumptions. Third, other oral opioid agonist treatment strategies such as buprenorphine or slow-release morphine, which are important options to improve the effectiveness of opioid agonist treatment, were not included in the model analysis and their inclusion in the model could affect the results on the cost-effectiveness of DAM or HDM. Lack of accessibility of these agents may limit the generalizability of rates of retention included in the model. Fourth, the model assumed only 1 state for relapse (defined by opioid use outside of treatment) and the individual left the treatment during relapse. In reality, some people may decide to remain on treatment despite relapse, and those who stay in treatment may have health advantage over those who do not.

The included guideline<sup>12</sup> recognized that the recommendations were made based on the low- to moderate-quality evidence because of the low number of studies and the discrepancy in evidence supporting each medication (i.e., DAM and HDM).

This review did not identify recent studies on the clinical effectiveness of DAM for injection in comparison with methadone or buprenorphine.

## Conclusions and Implications for Decision- or Policy-Making

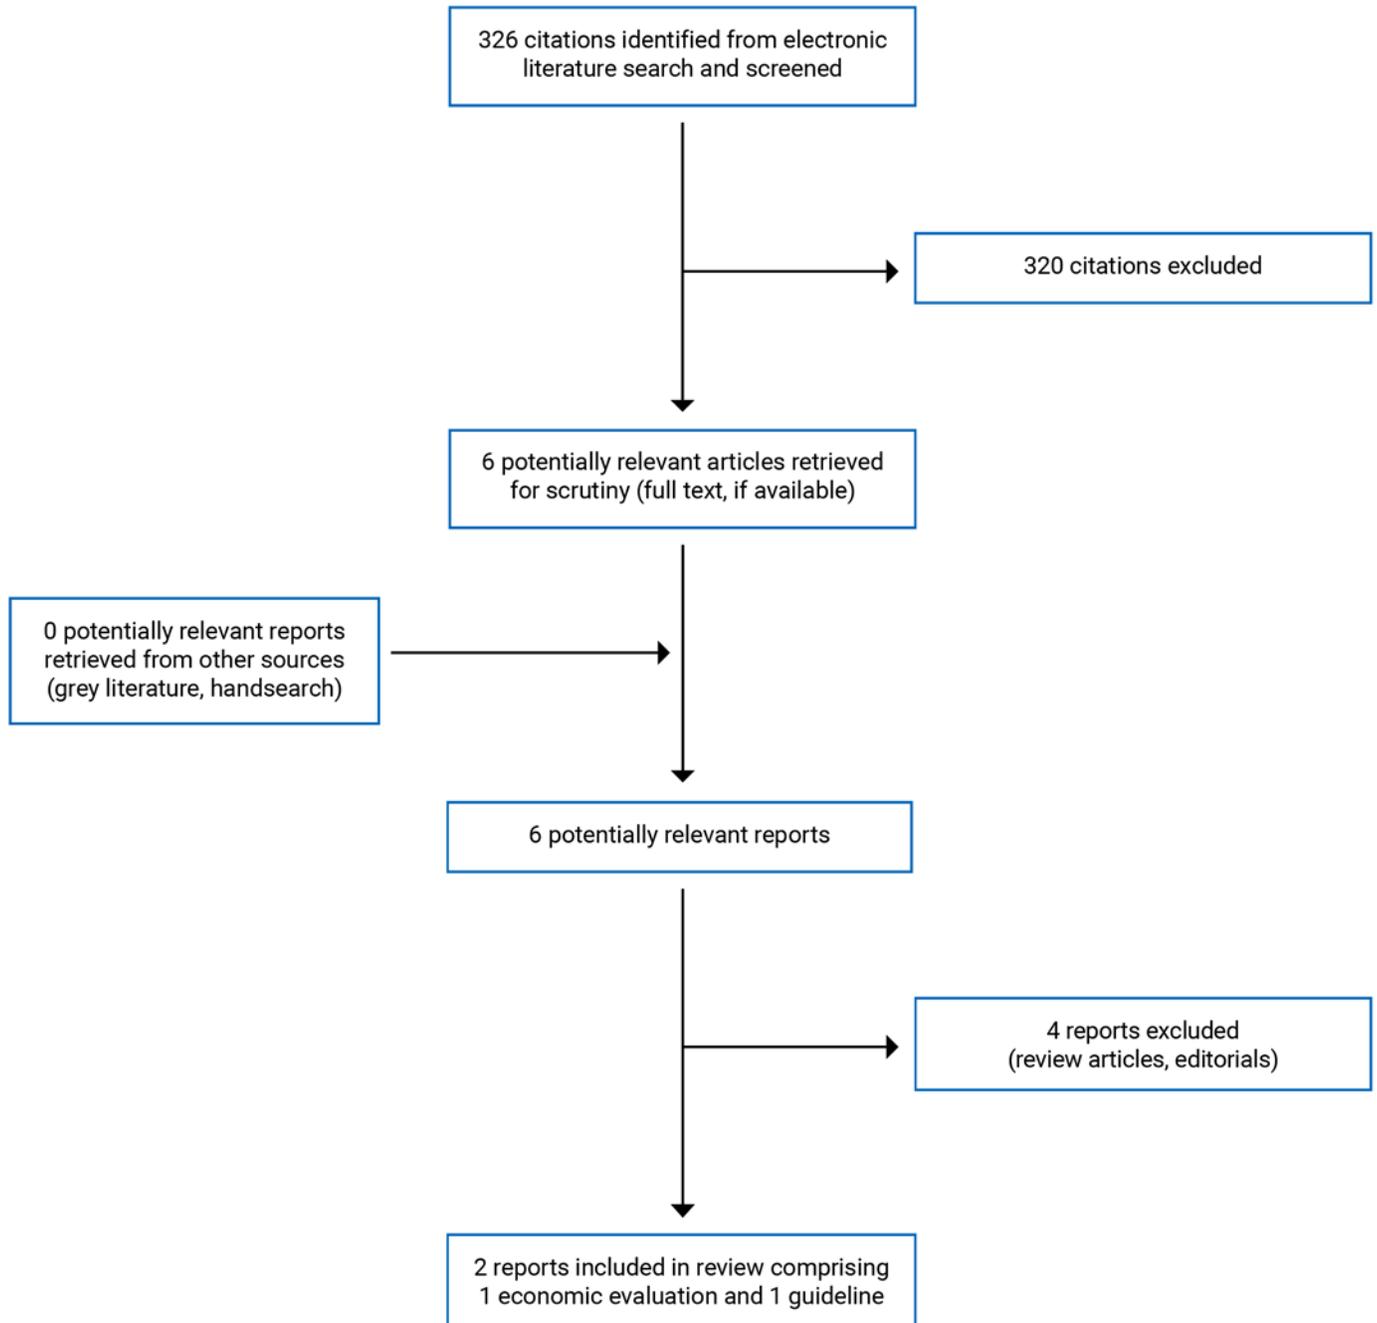

This report identified 1 economic evaluation study<sup>11</sup> and 1 evidence-based guideline<sup>12</sup> conducted by authors in Canada. The economic evaluation study results suggested that injectable DAM might provide more benefits and lower costs compared with oral MMT in patients with severe opioid use disorder. The majority (> 90%) of cost-saving was largely from reduced involvement in criminal activity. The findings of this economic evaluation study<sup>11</sup> on the comparison of DAM with oral MMT were inconsistent with those in previous studies in Canada and Europe.<sup>13,15,16</sup> No cost-effectiveness studies of injectable DAM compared with buprenorphine were identified. The CRISM guideline<sup>12</sup> provided 3 key recommendations on the patient populations considered for injectable opioid agonist treatment, medication selection, and treatment end date. The guideline recommends that both injectable DAM and HDM should be considered as treatment options for patients with severe, treatment-refractory opioid use disorder and ongoing illicit injection opioid use, and that the injectable opioid agonist treatment should have an end date to transition to oral opioid agonist treatment. The findings from the economic evaluation study and the recommendations of the CRISM guideline may be applicable to the Canadian context despite some limitations. Future studies are needed to compare the clinical effectiveness and cost-effectiveness of injectable DAM with other opioid agonist treatment strategies such as buprenorphine, slow-release morphine, or agents with any formulations.

**Table 3: Characteristics of the Included Guideline**

Intended users, target population	Intervention and practice considered	Major outcomes considered	Evidence collection, selection, and synthesis	Evidence quality assessment	Recommendations development and evaluation	Guideline validation
<b>CRISM, Fairbairn et al. (2019)<sup>12</sup></b>						
<p>Intended users: Canadian health professionals with clinical recommendations and guidance for the treatment of severe opioid use disorder with injectable opioid agonist treatment</p> <p>Target population: Adults with severe opioid use disorder</p>	<p>Injectable opioid agonist treatment (DAM or HDM)</p>	<p>High retention rates, reduction of street opioid use, and adverse events.</p>	<p>The evidence from literature was systematically identified.</p> <p>The medical writer reviewed, selected, and compiled evidence, including cost-effectiveness data, for the co-chairs and the guideline review panel.</p>	<p>Quality of evidence<sup>a</sup> was rated using GRADE.</p>	<p>Key questions were developed by the guideline review committee co-chairs in conjunction with the medical writer. Strength recommendations<sup>b</sup> were graded using GRADE tool.</p>	<p>The draft guideline recommendations were internally reviewed by the committee, and the feedback was addressed by the medical writer and committee co-chairs.</p> <p>The guideline was externally reviewed by the National Injectable Opioid Agonist Treatment Operational Guidance Review Committee. Ten international experts and 1 family member affected by opioid use disorder reviewed and provided input on the final draft.</p> <p>The guideline was published in a peer-reviewed journal.</p>

CRISM = Canadian Research Initiative in Substance Misuse; DAM = diacetylmorphine; GRADE = Grading of Recommendations Assessment, Development and Evaluation; HDM = hydromorphone.

<sup>a</sup>**High level of evidence:** Very confident that the true effect lies close to that of the estimate of the effect. **Moderate level of evidence:** Moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different. **Low level of evidence:** Confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect. **Very low level of evidence:** Very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

<sup>b</sup>**Strong recommendation for patients:** Most people in your situation would want the recommended course of action and only a small proportion would not; you should request discussion with your care provider if the intervention

is not offered. **Strong recommendation for clinicians:** Most patients should receive the recommended course of action; as an example, in this scenario, an algorithm or decision-making tool would not be necessary – the benefits of the recommended course of action would clearly outweigh any advantages of alternative interventions. **Strong recommendation for health care administrators:** The recommendation can be adopted as a policy in most situations. **Moderate strength recommendation for patients:** Most people in your situation would want the recommended course of action, but many would not. **Moderate strength recommendation for clinicians:** You should recognize that different choices will be appropriate for different patients and that you must help each patient to arrive at a management decision consistent with his or her values and preferences; in this scenario, an algorithm or decision-making tool would be advantageous to determine the best course of action. **Moderate strength recommendation for health care administrators:** Policy-making will require substantial debate and involvement of many stakeholders.

## Appendix 3: Critical Appraisal of Included Publications

Note that this appendix has not been copy-edited.

**Table 4: Strengths and Limitations of the Economic Evaluation Using the Drummond Checklist<sup>8</sup>**

Strengths	Limitations
<b>Bansback et al. (2018)<sup>11</sup></b>	
<b>Study design</b>	
<p>The study aimed to evaluate the cost-effectiveness of HDM compared with DAM and MMT. DAM was used as common comparator, so HDM was directly compared with DAM and indirectly compared with MMT. The study also compared DAM with MMT.</p> <p>The economic importance of the research question was stated that medically prescribed DAM is not available in Canada without special access due to regulatory and political reasons.</p> <p>The viewpoint of the analysis is stated that the model was constructed from a societal perspective.</p> <p>The rationale for choosing the alternative interventions and the alternatives being compared was clearly described. The SALOME trial was used to directly compare HDM with DAM, and the NAOMI trial was used to indirectly compare HDM with MMT.</p> <p>The study used an existing semi-Markov cohort model for the purposes of the analysis.</p>	<p>Other oral opioid agonist treatment strategies such as buprenorphine or slow-release morphine were not included in the model analysis.</p>
<b>Data collection</b>	
<p>The authors clearly stated the source of clinical efficacy data, which were obtained from 2 clinical trials, and data from an 11-year population study of methadone recipients in British Columbia.</p> <p>Details of the clinical effectiveness of the 2 trials were given.</p> <p>The primary end points for the economic evaluation were incremental costs, QALYs, and ICER from a societal perspective.</p> <p>The costs incorporated and resources used were clearly described.</p> <p>All costs were calculated by multiplying resource use by respective costs, adjusted to 2015 Canadian dollars, and discounted at 5% per year.</p> <p>Details of the model used were given.</p> <p>Key parameters incorporated into the model were clearly described.</p>	<p>Not all cost data were captured.</p>

Strengths	Limitations
<b>Analysis and interpretation of results</b>	
<p>A 50-year time horizon was used for the life-time analysis.</p> <p>All costs were adjusted to 2015 Canadian dollars and discounted at 5% per year.</p> <p>The study was explicit in terms of details of statistical tests and confidence intervals, approach to sensitivity analysis, choice of variables for sensitivity analysis, ranges over which the variables were varied, and incremental analysis.</p> <p>Major outcomes are presented in a disaggregated as well as aggregated form.</p> <p>Probabilistic analysis was used to estimate the means and 95% CIs of total costs, QALYs and ICERs to reflect parameter uncertainty.</p> <p>The results of the study answered the research question.</p> <p>The conclusion was made based on reported data.</p> <p>The conclusion was accompanied by the appropriate caveats.</p>	<p>The model assumed only 1 state for relapse (defined by opioid use outside of treatment) and the individual left the treatment when being relapse.</p>

CI = confidence interval; DAM = diacetylmorphine; HDM = hydromorphone; ICER = incremental cost-effectiveness ratio; MMT = methadone maintenance treatment; NAOMI = North American Opiate Medication Initiative; QALY = quality-adjusted life-year; SALOME = Study to Assess Long-term Opioid Medication Effectiveness.

**Table 5: Strengths and Limitations of the Guideline Using AGREE II<sup>9</sup>**

Item	CRISM, Fairbairn et al. (2019) <sup>12</sup>
<b>Domain 1: Scope and purpose</b>	
1. The overall objective(s) of the guideline is (are) specifically described.	Yes
2. The health question(s) covered by the guideline is (are) specifically described.	Yes
3. The population (e.g., patients, public) to whom the guideline is meant to apply is specifically described.	Yes
<b>Domain 2: Stakeholder involvement</b>	
4. The guideline development group includes individuals from all relevant professional groups.	Yes
5. The views and preferences of the target population (e.g., patients, public) have been sought.	Yes
6. The target users of the guideline are clearly defined.	Yes
<b>Domain 3: Rigour of development</b>	
7. Systematic methods were used to search for evidence.	Yes
8. The criteria for selecting the evidence are clearly described.	Yes
9. The strengths and limitations of the body of evidence are clearly described.	Yes
10. The methods for formulating the recommendations are clearly described.	Yes
11. The health benefits, side effects, and risks have been considered in formulating the recommendations.	Yes
12. There is an explicit link between the recommendations and the supporting evidence.	Yes

Item	CRISM, Fairbairn et al. (2019) <sup>12</sup>
13. The guideline has been externally reviewed by experts before its publication.	Yes
14. A procedure for updating the guideline is provided.	Yes
<b>Domain 4: Clarity of presentation</b>	
15. The recommendations are specific and unambiguous.	Yes
16. The different options for management of the condition or health issue are clearly presented.	Yes
17. Key recommendations are easily identifiable.	Yes
<b>Domain 5: Applicability</b>	
18. The guideline describes facilitators and barriers to its application.	Yes
19. The guideline provides advice and/or tools on how the recommendations can be put into practice.	Yes
20. The potential resource implications of applying the recommendations have been considered.	Yes
21. The guideline presents monitoring and/or auditing criteria.	Unclear
<b>Domain 6: Editorial independence</b>	
22. The views of the funding body have not influenced the content of the guideline.	No
23. Competing interests of guideline development group members have been recorded and addressed.	Yes

AGREE II = Appraisal of Guidelines for Research and Evaluation II; CRISM = Canadian Research Initiative in Substance Misuse.

## Appendix 4: Main Study Findings and Authors' Conclusions

Note that this appendix has not been copy-edited.

**Table 6: Summary of Findings of the Included Economic Evaluation**

Main study findings	Authors' conclusion
<b>Bansback et al. (2018)<sup>11</sup></b>	
<p>Life-years:</p> <ul style="list-style-type: none"> <li>• DAM: 18.4</li> <li>• HDM: 17.5</li> <li>• MMT: 14.9</li> </ul> <p>QALYs (95% CI):</p> <ul style="list-style-type: none"> <li>• DAM: 8.4 (7.4 to 9.5)</li> <li>• HDM: 8.3 (7.2 to 9.5)</li> <li>• MMT: 7.4 (6.5 to 8.3)</li> </ul> <p>Total costs (95% CI) during life-time:</p> <ul style="list-style-type: none"> <li>• DAM: \$1.01 million (\$0.68 to \$1.59 million)</li> <li>• HDM: \$1.02 million (\$0.72 to \$1.51 million)</li> <li>• MMT: \$1.15 million (\$0.71 to \$1.84 million)</li> </ul> <p>ICER (95% CI):</p> <ul style="list-style-type: none"> <li>• DAM vs. MMT: Ds (Ds, 306.8)</li> <li>• HDM vs. MMT: Ds (Ds, 883.7)</li> <li>• HDM vs. DAM: Dd (Ds, Dd)</li> </ul> <p>Probability of dominating MMT:</p> <ul style="list-style-type: none"> <li>• DAM: 75%</li> <li>• HDM: 67%</li> </ul> <p>Involvement of property crimes per person-year:</p> <ul style="list-style-type: none"> <li>• DAM: 9.6</li> <li>• HDM: 8.8</li> <li>• MMT: 15.0</li> </ul> <p>Decrease in criminal charges for property crime per person-year compared to MMT:</p> <ul style="list-style-type: none"> <li>• DAM: 0.3</li> <li>• HDM: 0.5</li> </ul> <p>For the comparison between DAM and MMT, the results were consistent in all scenarios, with the exception of the perspective taken (i.e., Ministry of Health).</p> <p>For the comparison between HDM and MMT, the results were consistent in all scenarios, with the exception of the price of medication and the perspective taken.</p>	<p>"In conclusion, our study finds that injectable HDM treatment is less costly and more beneficial than methadone treatment during a life-time predominantly through reducing the costs of involvement in violent and property criminal activity. In jurisdictions where DAM treatment is not available, not providing HDM treatment would add to the societal costs."<sup>11</sup> (p. 1271)</p>

CI = confidence interval; DAM = diacetylmorphine; Dd = dominated; Ds = dominates; HDM = hydromorphone; ICER = incremental cost-effectiveness ratio; MMT = methadone maintenance treatment; QALY = quality-adjusted life-year; vs. = versus.

**Table 7: Summary of Recommendations in the Included Guideline**

Recommendations and supporting evidence	Quality of evidence and strength of recommendations
<b>CRISM, Fairbairn et al. (2019)<sup>12</sup></b>	
<p><b>Injectable opioid agonist treatment:</b>                      “Injectable opioid agonist treatment should be considered for individuals with severe, treatment-refractory opioid use disorder and ongoing illicit injection opioid use.”<sup>12</sup> (p. E1053)                      Two SRs with MAs support this recommendation.</p>	<p>Level of evidence: Moderate                      Strength of recommendation: Conditional</p>
<p><b>Medication selection:</b>                      “For patients who are determined to be likely to benefit from injectable opioid agonist treatment, both diacetylmorphine and hydromorphone are acceptable treatment options.”<sup>12</sup> (p. E1053)                      Two SRs support this recommendation.</p>	<p>Level of evidence: Low                      Strength of recommendation: Strong</p>
<p><b>Treatment end date:</b>                      “Injectable opioid agonist treatment should be provided as an open-ended treatment, with decisions to transition to oral opioid agonist treatment made collaboratively with the patient.”<sup>12</sup> (p. E1053)                      Two post-RCT observational cohort studies support this recommendation.</p>	<p>Level of evidence: Low                      Strength of recommendation: Strong</p>

CRISM = Canadian Research Initiative in Substance Misuse; MA = meta-analysis; SR = systematic review.
