TITLE: Psychological Therapies in the Community Setting for the Prevention and Management of Suicides: Clinical Evidence

DATE: 31 May 2011

RESEARCH QUESTIONS

1. What is the evidence on interventions to prevent or manage suicides following the first attempt in adolescents and adults in a community setting?

2. What is the evidence on suicide prevention strategies in adolescents and adults in a community setting?

KEY MESSAGE

Although there are studies describing suicide prevention strategies in adolescents and adults in a community setting, there is limited evidence regarding the impact of these interventions.

METHODS

A limited literature search was conducted on key resources including PubMed, The Cochrane Library (2011, Issue 5), University of York Centre for Reviews and Dissemination (CRD) databases, Canadian and major international health technology agencies, as well as a focused Internet search. No filters were applied to limit the retrieval by study type. The search was also limited to English language documents published between January 1, 2006 and May 16, 2011. Internet links were provided, where available.

The summary of findings was prepared from the abstracts of the relevant information. Please note that data contained in abstracts may not always be an accurate reflection of the data contained within the full article.
RESULTS

Rapid Response reports are organized so that the higher quality evidence is presented first. Therefore, health technology assessment reports, systematic reviews, and meta-analyses are presented first. These are followed by randomized controlled trials and non-randomized studies.

One randomized controlled trial and one non-randomized study were identified regarding interventions to prevent or manage suicides following an attempt in adolescents and adults in a community setting. One systematic review, two randomized controlled trials and eight non-randomized studies were identified regarding suicide prevention strategies in adolescents and adults in a community setting. Additional references of potential interest can be found in the appendix.

OVERALL SUMMARY OF FINDINGS

One systematic review\(^1\) was identified that evaluated the effectiveness and safety of interventions for deliberate self-harm and attempted suicide, which included drug therapies, behavioural therapies, and community follow-up with the patient.

Two studies were identified regarding interventions to prevent or manage suicides following an attempt in adolescents and adults in a community setting. One randomized controlled trial\(^2\) compared the effectiveness of dialectical behavior therapy (DBT) with community treatment by experts and found that subjects receiving DBT were half as likely to make a suicide attempt as the community treatment group. In addition, a non-randomized study from Norway found that a community-based suicide prevention team did not significantly decrease the risk of a repeated suicide attempt within 6 months, 12 months, or 5 years after an attempt compared with treatment as usual.

Eight non-randomized studies were identified that described specific suicide prevention programs in adolescents and adults in a community setting\(^3-11\) and are summarized in Table 1.

</tbody>
</table>

Though it seems that community-based intervention programs may be effective in decreasing stigma associated with mental health issues and in decreasing suicidal attempts, it is unclear whether these programs have a significant impact on the rate of completed suicides. There is a lack of long-term follow up of subjects after completion of the intervention.
