TITLE: Anticholinergic Drugs for the Treatment of Overactive Bladder in Older Patients: Clinical Evidence, Safety, and Guidelines

DATE: 05 March 2012

RESEARCH QUESTIONS

1. What is the clinical evidence regarding any changes in cognitive function associated with the use of anticholinergic drugs for the treatment of overactive bladder in patients older than 65 years of age?

2. What is the clinical evidence regarding the safety of anticholinergic drugs, with or without cholinesterase inhibitors, for the treatment of overactive bladder in patients older than 65 years of age?

3. What are the evidence-based guidelines regarding the use of anticholinergic drugs for the treatment of overactive bladder in patients older than 65 years of age?

KEY MESSAGE

Seven clinical studies and one evidence-based guideline were identified regarding the use of anticholinergic drugs for the treatment of overactive bladder in patients older than 65 years of age.

METHODS

A limited literature search was conducted on key resources including PubMed, The Cochrane Library (2012, Issue 2), University of York Centre for Reviews and Dissemination (CRD) databases, Canadian and abbreviated list of major international health technology agencies, as well as a focused Internet search. No filters were applied to limit the retrieval by study type. Where possible, retrieval was limited to the human population. The search was also limited to English language documents published between January 1, 2007 and February 21, 2012. Internet links were provided, where available.
The summary of findings was prepared from the abstracts of the relevant information. Please note that data contained in abstracts may not always be an accurate reflection of the data contained within the full article.

RESULTS

Rapid Response reports are organized so that the higher quality evidence is presented first. Therefore, health technology assessment reports, systematic reviews, and meta-analyses are presented first. These are followed by randomized controlled trials, non-randomized studies, and evidence-based guidelines.

Two randomized controlled trials, five non-randomized studies, and one guideline were identified regarding the use of anticholinergic drugs for the treatment of overactive bladder in patients older than 65 years of age. No relevant health technology assessments, systematic reviews, or meta-analyses were identified. Additional references of potential interest are provided in the appendix.

OVERALL SUMMARY OF FINDINGS

No major changes to cognitive function, or safety issues, related to anticholinergic drugs were reported in any of the included studies.1-7 Further details of the included studies are provided in Table 1.

</table>

ER = extended-release; IR = immediate release.; NRS = non-randomized studies; OAB = overactive bladder; RCT = randomized controlled trial

The included evidence-based guideline⁸ indicates that the most common AEs experienced by patients using anticholinergic medications include dry mouth, blurred vision, dizzy spells, constipation, and urinary retention. Central nervous system effects such as cognitive disorders and confusion may also be experienced and may be of greatest concern for elderly patients. It is suggested that the efficacy of drugs for OAB be assessed at regular intervals.
