TITLE: Active Video Gaming and Virtual Reality for Children with Cerebral Palsy: Sustained Clinical Effectiveness

DATE: 8 September 2015

RESEARCH QUESTION

What is the long-term clinical effectiveness of active video gaming (AVG) or virtual reality (VR) for children with cerebral palsy (CP)?

KEY FINDINGS

One systematic review, three randomized controlled trials and two non-randomized studies were identified regarding the long-term clinical effectiveness of active video-gaming (AVG) or virtual reality (VR) for children with cerebral palsy (CP).

METHODS

A limited literature search was conducted on key resources including PubMed, The Cochrane Library, University of York Centre for Reviews and Dissemination (CRD) databases, Canadian and major international health technology agencies, as well as a focused Internet search. No filters were applied to limit the retrieval by study type. Where possible, retrieval was limited to the human population. The search was also limited to English language documents published between January 1, 2010 and August 21, 2015. Internet links were provided, where available.

The summary of findings was prepared from the abstracts of the relevant information. Please note that data contained in abstracts may not always be an accurate reflection of the data contained within the full article.

SELECTION CRITERIA

One reviewer screened citations and selected studies based on the inclusion criteria presented in Table 1.
Table 1: Selection Criteria

<table>
<thead>
<tr>
<th>Population</th>
<th>Children (aged 0 to 18) with cerebral palsy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intervention</td>
<td>Active video gaming or virtual reality</td>
</tr>
<tr>
<td>Comparator</td>
<td>None</td>
</tr>
<tr>
<td>Outcomes</td>
<td>Long-term clinical effectiveness (e.g., sustained improvements beyond the treatment intervention period in motor performance or control, balance, attention, tolerance)</td>
</tr>
<tr>
<td>Study Designs</td>
<td>Health technology assessments, systematic reviews, meta-analyses, randomized controlled trials, non-randomized studies</td>
</tr>
</tbody>
</table>

RESULTS

Rapid Response reports are organized so that the higher quality evidence is presented first. Therefore, health technology assessment reports, systematic reviews (SRs), and meta-analyses are presented first. These are followed by randomized controlled trials (RCTs), and non-randomized studies.

One SR, three RCTs and two non-randomized studies were identified regarding the long-term clinical effectiveness of active video-gaming (AVG) or virtual reality (VR) for children with cerebral palsy (CP). No relevant health technology assessments were identified.

Additional references of potential interest are provided in the appendix.

OVERALL SUMMARY OF FINDINGS

One SR, three RCTs, and two non-randomized studies were identified regarding the long-term clinical effectiveness of active video-gaming (AVG) or virtual reality (VR) for children with cerebral palsy (CP).

The SR reported results from studies investigating the effect of AVG on health outcomes in patients with various conditions, including CP. The overall consensus was that AVG improved health outcomes, including when it was compared to usual care. Disaggregated results specific to long-term follow-up and CP patients were not presented within the abstract.

The results of individual studies are summarized in Table 2. Overall, the RCTs suggested a long-term benefit for upper limb function with the use of AVG but no improvement in balance with the use of VR. The non-randomized studies reported positive long-term physical and functional outcomes with the use of AVG and VR.
